The case was that of a young man who had suffered from a patch of lupus vulgaris non-exedens since his eighteenth year. He had resorted to various methods of treatment under different medical men, but receiving no lasting benefit he substituted nonchalance for remedies. In his twenty-seventh year he contracted syphilis, developing in turn Hunterian chancre, bubo, sore throat, slight roseola, &c., and underwent mercurial treatment for two months. With the exception of occasional sores inside the mouth and slight debility nothing further accrued from the syphilis until the time I saw him. He came to me in March of this year and complained of sores on his left cheek spreading towards the lupus patch and slightly encroaching on the same. Towards the middle of the left cheek an irregularly oval patch of lupus vulgaris was to be seen with its long axis more or less parallel with the horizontal ramus of the lower jaw; it measured about 2½ in. in long diameter and 1½ in. in short diameter, with a small outstanding patch on either side stationed abreast. The patch was of a uniformly pinkish-red colour studded all over with apple-jelly nodules, but more especially so at the margin. There was no sign of breaking down or ulceration, but at one end was a small area in which the disease had disappeared and left some uneven scarring. Spreading over this in a fan-shaped fashion was the advancing crescentic ulcerating edge of a deep serpiginous syphilide. The syphilide appeared to have commenced in a broken-down nodule on the skin over the middle of the horizontal ramus and to have spread in a generally circular manner down the neck and over the cheek, leaving a pinkish white faintly pigmented scar. The pigmentation was more of a light brown mottling, the cicatrix was dense and tolerably even. When seen it had just invaded the lupus area and appeared likely to travel right over it.

On my advice the patient refrained from general treatment and I contented myself with applying mercurial plaster to the advancing edge on the neck. Cheekwards the disease advanced with some rapidity, mingling with the tissue of the lupus patch, the two combining to form ulceration which involved the whole depth of skin well down to the subcutaneous tissue. The skin on the lupus area broke down very readily on the approach of the syphilide, forming extensive ulceration. The edge of the ulcer was irregular and shreddy, not characterised by the punched-out steep edge of the syphilide *per se*, but marked by an unmethodical eroding; the base was foul, sloughing, reddish-grey in colour, and discharging freely a thin dirty liquid.

In the course of a week or ten days the ulceration had run over the greater extent of the patch, travelling most rapidly towards the left nostril. With the local application of iodoform ointment I now prescribed mercury internally, whereat the ulcerating process at once began to abate its fury, slowly at first, and only stopped when it had involved the whole lupus area, save the upper of the two small patches. Gradually increasing the mercury and after a few days adding small doses of iodide of potassium the base of the ulcer sloughed away, a healing edge began to encroach on the raw surface, granulation sprang up, and repair slowly went on to a close. In about eight or nine weeks a large purplish-brown cicatrix formed almost level with the surrounding skin, uniform and tolerably regular, and nothing remained of the lupus area except the small outstanding patch composed of a few lupomata and one or two nodules of the upper edge of the large patch which had escaped the ravages of the syphilide. To these I applied the galvano-cautery very thoroughly and dressed with a mild mercurial ointment. Shortly afterwards the patient went to sea.

In about three months I saw him again. The cicatrix over the lupus area had lost much of its pigmentation and had begun to assume a more purplish-white colour. Only one or two nodules of lupus were visible on the patch I burnt and to these I again applied the cautery. As a whole the scar is not very disfiguring, and to the patient is much less objectionable than the lupus with the risk of its progressive increase and disfigurement.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

"CONGENITAL ABSENCE OR DELAYED DEVELOPMENT OF THE PATELLA."

BY HAROLD N. MAYER, M.D. CHICAGO.

IN an article in THE LANCET under the above heading Mr. E. Muirhead Little[1] gave a summary of the recorded cases of absence of the patella with the extraordinary signs of degeneracy commonly associated with this condition. Dr. A. H. Burgess[2] has also described a case in which this bone was congenitally absent and which was associated with marked signs of degeneracy. There is at present in the infirmary on the poor farm in Chicago an individual who has congenital absence of the patella associated with most extraordinary stigmata of degeneration. His head, which is large, is decidedly asymmetrical, the left half of the face being somewhat larger than the right. The skull is exceedingly irregular in its osseous conformation. Both ears are very small and irregular and the ordinary auricular markings are not very apparent. There is microphthalmus of the right eye with apparently congenital haziness of the cornea. Most of the teeth have been lost but the dental arches are well formed. The arm and forearm are fairly well developed but each thumb is broad and both thumb-nails have a central groove. There is a rudimentary finger on each hand. Over the lower end of the sacrum is a fold of skin which rises somewhat above the surrounding level and conceals a slight opening in which a probe can be passed for about a depth of one-fourth of an inch. The testicles are undescended. The thighs are well formed with the exception of the absence of the patella. The knees are not in the position of hyperextension figured in Mr. Muirhead Little's article, but there is a certain amount of permanent flexion and the patient walks with them at nearly a right angle with the thigh. The feet are turned inward, so that if the leg were extended and he were standing upright pressure would be made directly upon the outer side of the foot. In the position in which he commonly moves, with the body bent upon the thighs and the legs flexed upon the thighs, he brings the soles of the feet in this position nearly parallel with a flat surface.

The individual is an imbecile and was exhibited at one time as part of a show under the title of the "Bear-Man,"

due to his peculiar method of locomotion. Later he developed delusions of suspicion, became somewhat unmanageable, and was finally brought to the almshouse.

A CAUTION AGAINST THE USE OF KEROSENE IN THE TREATMENT OF PEDICULOSIS CAPITIS.

BY MAURICE EDEN PAUL, M.D. BRUX., M.R.C.S. ENG., L.R.C.P. LOND.

ONE of the most convenient methods of treating pediculosis capitis is by rubbing the scalp and hair with kerosene. It instantly destroys the lice, it loosens the nits, and it soothes the cutaneous irritation. The recent death from burns consequent on the spontaneous ignition of hair that was being rubbed after the application of a hair-wash consisting principally of kerosene makes it necessary, however, to reject the use of kerosene as a parasiticide lotion to the hair. It appeared from the inquest in the above-mentioned case that the ignition of the hair was unquestionably not brought about by any naked light; and Lord Kelvin suggested (in a letter to the *Times*) that an explosive mixture of air and kerosene vapour having formed in the interstices of the hair this mixture was then ignited by an electric spark formed by friction of the hair. It is evident that no amount of care could guard against the repetition of this accident when kerosene was being applied to the hair.

LONDON TEMPERANCE HOSPITAL.

A CASE OF RUPTURED PYOSALPINX CLOSELY SIMULATING PERFORATION OF THE APPENDIX; NECROPSY.

(Under the care of Dr. SOLTAU FENWICK.)

THE difficulties of diagnosis in cases of localised peritonitis are very great, not with regard to the fact of peritonitis but with regard to the cause, and in the following case the pain situated in the hypogastric and right iliac regions was very suggestive of perforation of the vermiform appendix, but the pelvic signs pointed strongly to a pelvic origin of the disease. From the post-mortem examination it was obvious that there had been an attempt to localise the peritonitis, but this had failed and a general infection of the peritoneum had resulted. The commencement of the pyosalpinx probably occurred at the parturition twenty-one months before admission to the hospital.

A woman, aged thirty-nine years, was admitted into the London Temperance Hospital on Oct. 6th suffering from abdominal pain. The patient stated that she had been in good health until her second confinement twenty-one months previously, after which she was laid up for five weeks with "inflammation of the bowels." Since her recovery from that complaint the catamenia had appeared every fortnight, but she had never suffered from constipation, abdominal pain, or dyspepsia. Ten days before admission, while apparently in perfect health, she was seized with vomiting, which continued throughout the night and part of the next day. Under the impression that she was bilious she took a couple of pills which acted freely on the bowels. In the evening, however, she was suddenly attacked by severe pain in the abdomen. For the first few hours the umbilical and right iliac regions were the chief seat of the suffering, but subsequently the pain became diffused over the whole abdomen, and at the same time she felt feverish and thirsty. When admitted to the hospital the patient had the appearance of being extremely ill. The face was flushed and the tongue was furred; the pulse-rate was 112 and the temperature was 102·8° F. A liquid and offensive motion was passed soon afterwards, and several ounces of yellow bile were vomited. The tongue was moderately furred but moist, and the urine, which was voided without pain, contained a trace both of sugar and of albumin. On examination the lower half of the abdomen was found to be slightly distended and somewhat tender on pressure. The pain was chiefly referred to the hypogastric and right iliac regions, but neither tumour nor sense of resistance could be detected, while the percussion note was uniformly tympanitic. On vaginal examination the uterus was found to be rather low in the pelvis, and firmly fixed in the median line as though set in plaster-of-Paris. The finger inserted into the rectum encountered the same sense of resistance when pressure was made in a lateral direction, but no bulging or tumour could be felt, nor did the examination cause the patient undue pain. The other organs of the body were apparently normal. In view of these physical signs pelvic peritonitis was diagnosed, and the patient was ordered small doses of opium, while the abdomen was frequently fomented. On the following morning (the 7th) she appeared to be considerably better. The temperature had fallen to a point slightly over 101, the pulse and respiration had diminished in frequency, and little complaint was made of abdominal pain. On the 8th the temperature had fallen another degree, the pain was less troublesome, while in response to an enema a considerable quantity of fæcal material had been evacuated. The abdomen was still somewhat distended inferiorly, and pain was experienced on deep palpation over the region of the cæcum. There was no dulness on percussion over this part, nor could any localised fulness or tumour be detected by the finger in the rectum. After remaining in about the same state for two days the patient became markedly worse. The vomiting recurred and an access of pain in the lower part of the abdomen was complained of. The temperature rose to 103·4° and the pulse varied between 112 and 120. The abdomen was now found to be uniformly distended, and pressure over the right iliac region gave rise to pain and nausea. Comparative dulness on percussion was detected over the position of the cæcum, but there was neither swelling nor sense of resistance there or in the loin. Taking into consideration the gravity of the general symptoms, with the increased distension of the abdomen and the development of comparative dulness on percussion over the cæcum, it seemed probable that there was a collection of pus in the right side of the pelvis which was making its way behind the cæcum and coming forwards between that organ and the abdominal parietes like an ordinary perityphlitic abscess. A consultation was consequently arranged with Dr. W. J. Collins, who agreed to perform an exploratory operation early the following morning. Unfortunately, however, a few hours later the patient was attacked with collapse and rapidly succumbed.

Necropsy.—The small intestines were found to be greatly congested and spotted with flakes of lymph. On lifting the integuments covering the right iliac fossa and drawing the cæcum inwards a quantity of pus made its escape from beneath the bowel. On further examination a cavity containing about five ounces of pus was found to occupy the upper part of the right half of the pelvis, the internal wall of the sac being formed by the uterus and numerous old adhesions existing between that organ and the other pelvic viscera; while its upper boundary consisted of several adherent coils of small gut. Hanging in the middle of the abscess cavity was a well developed and perfectly healthy vermiform appendix. In close proximity to it was a pyosalpinx of the right Fallopian tube resembling a small walnut in size and shape, the rupture of which was responsible for the pelvic inflammation.

LIVERPOOL NORTHERN HOSPITAL.

A CASE OF ACUTE GENERAL SUPPURATIVE PERITONITIS TREATED BY LAPAROTOMY; RECOVERY.

(Under the care of Mr. CHAUNCY PUZEY.)

IN THE LANCET of Oct. 9th, 1897, p. 916, we published a case of acute general peritonitis under the care of Mr. Leonard Gamgee in which recovery followed the washing out of the abdominal cavity, and a fair number of cases are now on record in which this treatment has proved successful; but the mortality mus always remain high for many of the

Digitized by Google

patients do not come under treatment until the peritonitis has lasted several days. Of twenty-five cases in the Berlin Charité only five recovered.[1] Quite recently Dr. J. M. T. Finney,[2] in the "Johns Hopkins Hospital Bulletin," has advocated the thorough and systematic wiping out of the whole peritoneal cavity with large pledgets of gauze after allowing all or as much as is necessary of the small intestine to escape from the abdominal cavity, then each loop of the small intestine is to be wiped carefully while still outside the abdomen; his method has proved successful in five consecutive cases and so is deserving of consideration. Others are opposed to anything more than simple incision with free evacuation of the infected effusion and the results are certainly remarkable. It is highly desirable that in all cases of acute suppurative peritonitis a careful bacteriological examination should be made of the pus.

A boy, aged fifteen years, was on May 31st, 1897, sent into the Liverpool Northern Hospital as a case of intestinal obstruction. The patient presented a wasted and collapsed appearance and was too ill to give any satisfactory history of his illness, and his parents appeared to know little about him. Later, it was ascertained that three weeks before admission he had been bathing in a dirty canal and, on returning home, "began shivering." On the next day he went to work feeling pretty well. A week later he "felt a dreadful pain" in his abdomen but went to work in pain all the next week. Then he went to a "doctor" (? druggist) who gave him a black draught, which did him no good. So he went to bed, and lay there for a week, suffering from pain and sickness, but without medical attendance. Then a medical man was sent for, who ordered his immediate removal to hospital.

The patient's symptoms on his admission, in addition to the general appearance before mentioned (a most marked facies abdominalis), were tenderness and moderate distension of the abdomen, with rigid muscles; the knees were only slightly drawn up; the tenderness was most marked in the left loin and pelvis, where there seemed to be most feeling of resistance on pressure, and where there was also dulness on percussion. The bowels had been slightly moved twenty-four hours previously; but since then, neither fæces nor flatus had been passed. There was occasional vomiting of offensive, but hardly fæculent fluid. The tongue was dry down the middle and furred; the pulse was 120 and the temperature was 100° F. Rectal examination discovered a soft mass somewhat resembling an intussusception; and on this supposition, an indiarubber tube was passed up the bowel as far as practicable, a glass funnel attached, and the pelvis being raised and the anus firmly occluded, about two pints of hot water were gradually poured into the bowel, until the patient complained of pain. On removing the tube, and passing the finger into the rectum, the obstruction had disappeared, and the rectum felt widely distended. Very little of the fluid returned. It must have been absorbed; for he passed large quantities of highly coloured urine, although he was taking no fluid by the mouth. One-sixth of a grain of morphia was given subcutaneously, and he seemed easier; the pulse was stronger and the fulness in the left flank was less marked. On the next day (June 1st) the patient's condition was much the same, and on examination the obstruction in the rectum was again found, but was less marked. The irrigation was repeated and again the obstruction disappeared. The boy's parents had refused consent to anything more being done, but on the next day, his condition being decidedly worse and the vomiting more distressing, they consented to an operation; and it was decided to explore the abdomen without further loss of time.

This operation was performed under ether after the usual preliminary cleansing of the abdominal wall. An incision three and a half inches long was made in the middle line between the umbilicus and pubes. On opening the peritoneum, which was partly adherent to the intestine, a drachm or two of thin fœtid fluid escaped. The intestines were moderately distended and were matted together by thick lymph. On separating the adhesions the masses of lymph peeled off like rotten wash-leather, leaving freely oozing intestinal walls. Working down with the fingers towards the left brim of the pelvis several ounces (probably about half a pint) of intensely foul, purulent fluid escaped. In one part of the cavity thus opened up two or three small purplish lumps like squeezed-out grapes were noticed, and it was suggested that these were mesenteric glands which had suppurated and burst on to the peritoneal surface and had thus set up the mischief. The abdominal cavity was next flushed out as thoroughly as possible with hot boracic acid solution and afterwards with izal lotion (half an ounce to the pint), the edges of the wound being occasionally held together and the abdominal cavity distended with the solution, the funnel being raised two or three feet. The abdominal wound was now closed in the usual manner for the upper three-fourths, the lower fourth being left open, and a large glass drainage-tube fixed in, reaching to the deepest part of the pelvis. The dressing used then and throughout the subsequent treatment of the case was iodoform powder, cyanide gauze, and salicylic wool, fixed on with a wide muslin bandage, so as to exert moderate compression of the abdomen.

From this time the patient's progress towards recovery was slow but continuous with one exception. Eight days after the operation, the temperature, which had been subnormal, rose to 101° F., the tongue which had been clean and moist, again became dry and furred, and the discharge from the tube became fœtid. The tube was removed, the flushing apparatus was adjusted, and the abdominal cavity was once more thoroughly washed out with izal solution; after this, the left flank which had always remained rather full and tender, soon became softer and free from pain; and subsequently, there was very little discharge from the wound, and that was serous and odourless. The bowels were moved naturally on the third day, and with an enema on the sixth and seventh days after operation. After that with an occasional enema they acted regularly. Before the operation and for several days after alimentation was principally by means of rectal suppositories; but for brevity's sake, details on this and other points are omitted. In consequence of the boy's feeble condition union of the wound was very weak, so that the stitches were left in until they threatened to ulcerate out, and it was necessary to remove them and to support the edges of the wound with strapping. Fortunately the peritoneum had been stitched up separately with a continuous buried suture, so that there was no actual re-opening of the wound. The sinus resulting from the drainage-tube was not completely closed for two months. At that time it was noticed that there was a slight tendency to hernia at the upper part of the cicatrix, so a pad was applied over that part and the abdomen supported with an elastic bandage. The boy was sent to Woolton Convalescent Institution early in September. He was fat and well and free from any abdominal trouble. He came to the hospital on his return from Woolton to be examined. The hernial protrusion was no longer to be observed, but when he coughed the two recti muscles stood out separately from each other; so he will continue to wear the elastic bandage, which he himself applies every morning before getting out of bed. It should be noted that he has been carefully examined and that no trace of tuberculosis can be found, so the case was not one of tuberculous peritonitis.

Remarks by Mr. CHAUNCY PUZEY.—The subject of operative treatment of suppurative peritonitis having been brought forward somewhat prominently of late this case may prove of interest, especially as it presents some unusual features. Most of the cases published have been probably due to mischief about the cæcum or appendix; but in this instance the trouble must have arisen from some other cause, although the meagre history obtainable gave but little clue to its real origin. Still, the successful result of exploratory operation and of thorough flushing of the peritoneum furnishes an additional instance of this comparatively modern method of treatment.

SANITARY CONDITION OF ST. COLUMB MINOR, CORNWALL.—At the meeting of the St. Columb Major District Council, held on Nov. 18th, Dr. J C. Mackay, the medical officer of health, in reporting upon the village of St. Columb Minor stated "that the sanitary condition of this village is something awful; nothing approaching it exists anywhere else in the district. So far back as 1884 I made a special report, in 1889 reported that the place was only to be compared with a sewage farm, and in 1892 a special complaint was made against the Highway Board for permitting their roads to be converted into a common sewer. The only comment made by your board was, "Query, where"? I have reported adversely on St. Columb Minor at least a score of times, but it still constitutes a danger."

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Discussion on the Prevention of Enteric Fever.

A MEETING of this society was held on Nov. 23rd, the President, Dr. HOWSHIP DICKINSON, being in the chair.

The discussion was opened by Dr. G. V. POORE, who commenced by stating that the contagion of enteric fever is contained in the excreta and may gain access to the bodies of the healthy in drink or food or air. When enteric fever becomes suddenly epidemic it is most often through contamination of the drinking water and sometimes through the water of the milk or other beverages. Short records were given of forty-six instances within the last thirty years of contamination of public water-supplies, and in twenty-nine instances where the figures were given the number of cases amounts to 16,486. These public water-supplies were contaminated either at the source, in their course, or at the periphery. Of the contaminated sources eight were streams and rivers, eleven were wells, and three were upland gathering grounds. Of the polluted wells seven were deep wells in the chalk. These chalk wells were polluted by leakage from a sewer (2), by accidental defilement of an adit (1), by the tricklings from the surface of an adjacent sewage farm (1), by back flow from a river (1), and by leakages from foul ponds and cesspools (2). Those sources of water which are farthest removed from dense populations are probably safest, but moorland waters are not free from risks; some of them act unduly upon lead; and it is interesting that Glasgow in 1881–90 had a mortality from enteric fever slightly higher than the average for England and Wales. Given the fact of contamination, wells and springs are dangerous because there is no escape for the polluting matter except into the supply-pipes. Water from uplands has undergone no filtration before reaching reservoirs. In rivers we get the advantage of oxidisation and sunlight, and only a small proportion of polluting matter at most is likely to be taken up. With regard to pollution in the course, the most common cause is the insuction of foul air or liquid by leaking water-pipes during intermissions in the supply. This insuction is especially apt to occur where there is an intermittent supply and the fouling of the water pipes is facilitated by the insanitary practice of laying the sewers and water-pipes side by side inaccessible to observation. Both should be laid in subways so that they could be easily inspected. Pollution at the periphery—i.e., through the taps—is most important. It is liable to occur whenever a tap is left turned on and a vacuum is produced in the supply-pipe by intermission of supply, so that foul gas or liquid or even solids are sucked back into the house pipe or main. An instance of this had been described by the late Sir G. Buchanan. When investigating an outbreak at Croydon he was told that in one house the water tap on certain days yielded blood. This was found to be due to the existence of a slaughter-house next door. At a recent outbreak of enteric fever among the staff of University College Hospital it was found to be due to such aspiration. Alterations had necessitated the fitting up of a temporary dining-room for the nurses and water was required for a sink. The water-supply was taken by the plumber from the nearest pipe, which also supplied the tank in which the linen from some cases of enteric fever had been washed, and some of the infectious material must have been drawn back from this tank and have contaminated the drinking water. This peripheral pollution is well understood and its frequent occurrence raises a doubt whether the abolition of the house cistern does not endanger the purity of the water flowing in the mains. The maintenance of constant pressure in the pipes, although theoretically desirable, is not practically attainable at all times. The liability to peripheral pollution raises the question whether all public supplies are not liable to a certain small extent to automatic pollution. It must be remembered that in big towns there are many foul places other than water-closets over which there may be open taps. A common source of peripheral pollution is the leakage of standpipes (as occurred at Worthing), and the flooding of the street with sewage, as often happens when drains are flooded out by storm water. Public water-supplies must be regarded as causes of the epidemicity of enteric fever. They diffuse the poison with a completeness which is absolute, and ensure that it is "laid on" as it were to our very mouths through being used not only for drinking but also for washing dairy cans, oysters, salads, &c. These epidemics show the danger of "putting too many eggs in the basket," and the necessity of arranging water supplies with as many independent subdivisions as may be feasible and of never mingling supplies from different sources. A staff of chemists and bacteriologists should be maintained by the water companies just as by the large dairies. Water-pipes and sewer-pipes should be placed in subways if possible so as to be open to ready inspection, or one set of pipes should enter at the front of a house and the other leave by the back. To have them running in close proximity and out of sight is attended with obvious danger. Water companies should be made answerable for damage just as are other trading companies and the householder ought to have the right of being supplied by meter. It is impossible to see much increase of safety in handing over water-supplies to the care of public bodies where individual responsibility is non-existent. Our safety lies in vigilance. The notifications of enteric fever should be forwarded at once to the water authorities and the sewer authorities, and the companies should guard their supplies with a constant vigilance such as is exercised by the great dairy companies. Careless or wilful waste of water (when not supplied by meter) should be punishable by fine. Plumbers who attend to drains and sewers ought not to touch water-pipes and cisterns without a complete washing and change of raiment. In the treatment of excreta chemical disinfection is untrustworthy. Burning is the most certain mode of destruction. Enteric excreta should never be mixed with water because it is pre-eminently a water-borne disease and the property of water is to return to its source. This is illustrated by familiar examples, thus: water-closet, sewer, sea, oyster. It is said that sewage is good for our fisheries. At present we have distinct evidence of evil and none of good. Again: water-closet, leaking sewer, chalk well, drinking-water; or water-closet, sewer, river, watercress, drinking-water; or water-closet, leaking sewer, leaking water-pipe, drinking-water; or water-closet, cesspool, shallow well, milk; or (as at Caius College) fæces may be sucked directly from the water-closet into the water-pipes. The great cause of the increase and wide epidemicity of enteric fever in recent years has been the water-closet which was invented by Bramah at the end of the last century. The year 1849, in which the non-identity of typhus fever and typhoid fever was settled by Sir William Jenner, was the year of cholera, the year of the Broad-street pump, the year in which the great fact of water-borne disease was established. The conditions which gave us the great outburst of cholera in 1849, when the Thames was at once our cesspool and our source of water, were eminently calculated to furnish sufficient enteric fever to establish its identity. Dr. William Farr fully recognised that the cholera epidemic of 1849 was attributable to the water-closet, but he hoped that by better management our drinking-water might escape pollution. When water leaks incessantly from one spot (whether it be cesspool or sewer) it soon begins to exercise pressure and may trickle any distance. A drain-pipe or sewer is quite as dangerous for the water-supply as a cesspool. It is probable that the dry privy of our ancestors had a very slight polluting effect upon the soil. In old arrangements each house had its own well in the neighbourhood, and with all its advantages this must have tended to keep the subsoil dry; but the present system of water-supply had, if anything, an opposite effect, and this increased dampness of the soil round houses must not be lost sight of as a factor in the production of disease. Enteric stools in country places may quite safely be applied to the surface of well-tilled soil. They must not be mixed with antiseptics and must not be buried deeply. There is no evidence that fæces treated in this way have ever been productive of harm. Dr. Poore, speaking with an experience of fourteen years, was convinced that fæces cannot be washed out of well-tilled humus by any amount of rain. In such a position the bacilli are almost certainly destroyed, for in tillage they are exposed to air and sunshine. In such a position they are not likely to be eaten or drunk, and there is very little likelihood of their being raised as dust, for they are very hygroscopic. In such a position fæces disappear in a few weeks. A well-tilled humus is probably the most perfect protection to our water-supplies conceivable, as he had set forth at length in his published works. The fact

Digitized by Google

that the enteric bacillus will live in sterilised soil does not prove that the soil is dangerous when properly managed. The fact that microbes will live in gelatin has merely taught us how to avoid the dangers of gelatinous food, which is as popular as ever. The pollution of the soil in our great towns is due to the incessant soaking, from spilling excess of water and dirty fluids, and from the leakage of subterranean receptacles of liquid filth of all kinds. A thick layer of well-tilled humus was a great protection for deep water-supply. There can be no purity of soil without tillage and organic filth must be placed upon the humus to increase our food-supply and not beneath it to endanger our water-supply. Dr. Poore did not think it at all likely that town populations would hastily abandon their water-closets (in London it seems impossible), but he considered it was time that the people were taught that excreta properly used might be a source of health, wealth, and beauty. This important matter holds no place in our national education. There are no municipal gardens for demonstrating how excreta may increase the attractiveness and prosperity of a district. On the contrary, our populations are silently taught that the only decent (!) way of treating fæces is to mix them with water, to brew sewer gas, and ensure the aerial as well as the aquatic convection of enteric fever. A man who has a house with a quarter of an acre of ground may be perfectly independent of the sanitary authority and may get good water from a private well. But such persons who really try to keep their houses clean and wholesome receive no encouragement in the present state of the sanitary laws.

Professor GAIRDNER (Glasgow) said that his connexion with sanitary duties had been interrupted many years ago and that he had little recent experience. He well remembered an occasion when Murchison brought before that society a paper in which was the germ of the classical treatise on Continued Fevers. The current doctrine at that time was that enteric fever was due to sewer gas. In Glasgow many epidemics had been traced to the milk-supply, and it was found that the milk was brought in from a distance and that the contamination occurred there and not in the city, and therefore Dr. Poore should not contend that the death-rate from enteric fever in Glasgow was associated with the fact that they drew their supply from the moors. He wished to testify, as Dr. Poore had done, to the industry and ability which had been displayed both by the local medical men and the officers of the Local Government Board in tracing the actual cause of the various epidemics. Under the old arrangements the local medical men were afraid to point out insanitary dairies because they would have been liable to troublesome litigation. Now the public official, the medical officer of health, could do so without that risk to the great advantage of the community. Professor Gairdner concluded by mentioning an epidemic which occurred among the students which was at once stopped when the supply of milk at the restaurant within the university was forbidden.

Sir RICHARD THORNE said that he gathered that broadly Dr. Poore regarded as the principal evils our sewers, water-closets, and our system of water-supply, and that the remedies that he would suggest were the general use of dry closets, a return to shallow wells, and the deposition of the excrement on well-tilled soil. It would be gathered from Dr. Poore's remarks that the system of water-supply was fraught with danger to the country. But was this borne out by facts? Since 1875 millions had been spent in this country on works for providing the towns with a water-supply. At the beginning of that period the death-rate from enteric fever was 0·37, and at the present time was only 0·17, showing a great saving of life. Though enteric fever now assumed an epidemic form the total death-rate was much lower than when it was endemic. Dr. Poore had spoken of the death-rate from enteric fever in Glasgow as being somewhat higher than that of other large towns, and had been inclined to attribute it to the fact that Glasgow derived its water-supply from uplands. But the present death-rate should be compared not with that of other large towns but with that of Glasgow before the drawing of water from this source. It then appeared that the annual death-rate from 1865 to 1879 was 510 per 1,000,000, and that during the last ten years it had fallen to 193 per 1,000,000. Dr. Poore had also referred incidentally to the spread of cholera through the water-supply, and no doubt it had occurred. But taking the mortality as a whole, while in old epidemics there were as many as 50,000 deaths, in one under the new conditions there were only 135 deaths. Many of the faults attributed to the system of water-supply were due to defective work, leaky sewers, and badly jointed water-pipes. But it was not just to condemn the whole system because it was imperfectly carried out. He (the speaker) most emphatically agreed that the water companies should be made responsible for the quality of the water that they supplied. But the fault lay with the public, who through their Parliamentary representatives allowed clauses to be inserted into Acts of Parliament which protected the companies. As regards Dr. Poore's remedies he did not see how in the existing state of affairs in urban districts it was possible to adopt the use of dry closets with daily removal of excreta to be used on well-tilled soil in the sight of all, although it might be an ideal arrangement in an Adamic stage of civilisation. Except in certain conditions in country districts he thought that the return to the use of shallow wells, which he understood Dr. Poore to advocate, would be infinitely more dangerous than the present system. It was with such wells that the disease was formerly endemic with a much higher total death-rate than now. As regarded the effect of putting excreta on land he admitted that with thorough tillage there was little risk of water contamination; but how was this to be carried out as a universal system especially in the face of the increasing scarcity of agricultural labour? Besides, although the method might be safe with ordinary dejecta it was yet to be proved that it would be so in the case of specific excreta. Experiments had been made by Dr. Martin for the Local Government Board to try to find the reason for the occasional persistence of enteric fever in a particular locality. He found that typhoid bacilli would only grow for a few days in sterlised virgin soil, but that in soil containing sewage which had been sterilised in a similar manner growth went on for 200 days. It had also been shown by others that in soil containing sewage typhoid bacilli would remain quiescent during the winter and begin to grow rapidly when the warm weather returned. He fully agreed that burning was a safer method than burial for dealing with the excreta. The best plan was to mix them with saw-dust and paraffin and burn them. There were two sides to the question, and while Dr. Poore's suggestions might be carried out in some rural districts he did not think that they were applicable to our present conditions in large towns.

Professor RUBERT BOYCE (Liverpool) desired to put in a strong plea for systematic bacteriological examination as a most important means of preventing epidemics of enteric fever. During the last three years he had been making bacteriological examinations of the various vehicles by which the contagion was conveyed. 1. A sewage bacteriological station was now being arranged for the systematic examination of the contents of the drains. Examinations of the intake and output of the sewage farm were systematically made and compared, and in this way a "flora" of the organisms ordinarily found in sewage was being prepared. Pupils in the engineering department were sent to a course of bacteriology so that they might undertake this work. 2. Constant bacterioscopic investigation of the drinking water. This will lead to the abolition of wells and cisterns for private use. The water must be examined at different points, before and after filtration, in the supply pipes and as it issues from the taps. Systematic observations of this kind would enable any bacterial impurity to be traced and its mode of entrance into the water discovered. 3. Bacterioscopic examination of the milk and milk products such as cream, butter, ice-cream, and cheese. 4. Bacteriological examination of shellfish, oysters, &c. In from one-half to one-third of these the colon bacillus was found in abundance. Dr. Newsholme and others had started bacteriological laboratories in connexion with the department of the medical officer of health, and he hoped that this example would be generally followed.

Dr. D. S. DAVIES (Bristol) gave an interesting account of an epidemic which recently broke out in Clifton. Both Clifton and Bristol had previously enjoyed remarkable immunity from enteric fever, but on Oct. 21st, 1897, the occurrence of some definite cases of enteric fever led Dr. Davies to suspect that the "influenza" which was currently reported to be prevalent might prove to be enteric fever, and on examining many of these cases their blood was found to give the Widal-Grünbaum reaction. Four days' investigation showed that milk was the vehicle of infection and when the milk-supply was cut off the epidemic rapidly

Digitized by Google

subsided. During the last five weeks the number of notifications were 16, 100, 60, 19, and 10. Charts were shown illustrating the milk-supply. It was clearly shown that most of the cases occurred in houses supplied by one particular dairy. The others occurred in houses supplied from dairies which were in perfect order, but it was found that the distributors from these two dairies were in the habit of supplementing their supply by buying some from the man who was delivering the infected milk. Fifty-seven houses were supplied from the infected dairy and thirty-one of these were attacked. In the case of the other two milk-supplies there was a comparatively small quantity of infected milk and the proportion of houses attacked was smaller. One school in which sixty-three persons lived was supplied with the infected milk, but the milk was always scalded and not a single case of enteric fever occurred. In another house a woman attacked was the only one who drank unboiled milk. It was found that the infected milk came from a farm in a village where the brook was utilised as the main sewer. This brook ran through the chief dairy farms and no doubt was the cause of the pollution. The remedy suggested by Dr. Davies for this state of things was an arrangement by which each urban authority might be empowered to inspect, register and license outside dairy farms and farmers who furnish their supplies to the exclusion of unlicensed places and persons. In default of some enactment such as this there ought to be a voluntary association of the contractors themselves to coöperate with the sanitary authorities and submit to certain regulations and frequent analyses of the milk and inspection of the dairies.

The further discussion was adjourned until the next meeting of the society.

MEDICAL SOCIETY OF LONDON.

Treatment of Pyo-pneumothorax.—Mechano-therapy of Moveable Kidney.

A MEETING of this society was held on Nov. 22nd, the President, Dr. SANSOM, being in the chair.

Dr. SAMUEL WEST read a paper on a case of Pyo-pneumothorax of some months' duration cured by free incision. The patient, a man, thirty-four years of age, came under observation with left pneumothorax and sero-purulent effusion of four or five months' standing. The patient, who had already been under other treatment for some time, being very ill, incapacitated from work, and getting worse, it was decided to incise the chest rather than perform paracentesis, on the ground that in such cases the results of paracentesis were discouraging, that the patient would evidently die if nothing was done, and that on general principles free incision seemed indicated. The side was opened by a simple incision, about four pints of sero-purulent fluid were removed, and a drainage-tube was inserted. The next day the lung had expanded and was in contact with the chest-walls everywhere except round the incision. The discharge was profuse for a few days and then became very scanty. Within a few days nothing of the pleural cavity was left except the track in which the tube lay. The patient rapidly improved, but the tube could not be got rid of until seven months from the time of the operation. The case had been previously dismissed from another hospital as incurable. As a rule these cases are left alone owing to a belief that the lung is bound down and cannot expand. Cases were quoted and reasons given for not accepting this as the rule or even as frequent. Another false notion is that pneumothorax is generally associated with tuberculous disease of the lung and that it is good for a tuberculous lung to be compressed by air or fluid because the progress of tubercle in it is arrested. This reason, often given, was shown to be an opinion only and not supported by facts. Dr. West reminded the society that the same reasons were formerly also given for leaving serous effusions and empyemata alone; they are not now regarded as valid against the removal of the effusion in these cases and are therefore not valid in pneumothorax. It has also been held that incision does no good but rather hastens the inevitable death. Statistics are often quoted in support of this statement, but they are old statistics and should no more settle the question in pyo-pneumothorax than they would be allowed to settle it in empyema. If empyema were neglected nowadays as long as pyo-pneumothorax usually is the results would be no better; *per contra*, if pyo-pneumothorax comes to be treated on the same general principles as empyema a similar improvement in results may be naturally anticipated. Dr. West considered that incision might become necessary (1) in the early stage if the dyspnœa and symptoms were urgent and not relieved permanently by paracentesis (in this stage the necessity would rarely arise); and (2) in the later stages—(*a*) if no fluid formed incision would never be necessary; (*b*) if the effusion were purulent incision would be the proper mode of treatment and the only one which would offer hope of success; and (*c*) if the effusion were serous incision might become the right mode of treatment as in certain cases of obstinate serous pleurisy. In conclusion pneumothorax should be treated on general common-sense principles, the presence of air not affecting the general principles in any way, but only introducing certain modifications in carrying them into effect.—Dr. DE HAVILLAND HALL said that he was very much interested in the proposal that Dr. West had supported with so much ability to subject cases of pyo-pneumothorax to the same treatment as those of empyema, but he thought that the view taken of the result would prove too sanguine in those cases in which the lung did become firmly bound down and would not re-expand. He mentioned one case of empyema in which this was the case, and although extensive resection of ribs was resorted to the patient ultimately died unrelieved. Such cases were fortunately rare, and he thought that the majority of cases would do well if treated with free incision. One very important factor would be the condition of the lung prior to the occurrence of the pneumothorax and the chances would be very much better for a patient whose lung was fairly healthy, and he did not suppose that Dr. West would suggest operation in cases where the lungs were riddled with cavities. He quoted cases of this kind in which the necropsy showed that operation could not have benefited the patient. He mentioned a case quoted by the late Sir Andrew Clark of a man who for some years came up periodically to have the signs of pyo-pneumothorax demonstrated. During Sir Andrew Clark's absence a colleague had the chest incised, but the result was unsatisfactory and the patient died.—Dr. THOROWGOOD agreed in the main with the proposal to treat these cases on the same lines as cases of empyema, but did not think that there was the same indication for immediate operation, and thought that each must be considered by itself and he would only advise operation if the symptoms were urgent. He was glad that Dr. West had scouted the ridiculous theory that tuberculous disease of the lungs was checked by compression through the presence of fluid in the pleural cavity.—Mr. MARMADUKE SHEILD said that at the request of Dr. Ewart he had operated on a case of pyo-pneumothorax complicating gangrene of the lung. The patient was apparently moribund and the operation was performed as expeditiously as possible and a rapid, unexpected recovery took place. He had also operated in a case in which signs of the presence of fluid and air in the chest had existed for six months. The lung was found to be firmly bound down and a cavity was left which would not close. He did not perform Estlander's operation as he was not favourably impressed with the results. The patient died from exhaustion. Special care was required in these cases in giving the anæsthetic. The unaffected side should be left free and a minimum of anæsthetic used. He made a "trap-door" incision, which enabled him to deal rapidly if necessary with several ribs, and after the operation he preferred not to use a fixed dressing but to employ moveable pads of wood-wool and iodoform gauze on which the patient lay with the incision dependent. The pad could be frequently changed by the nurse and the position of the patient and the absence of a bandage allowed the unaffected lung to have free play. In cases of pneumothorax from traumatism nothing should be done, as the air was almost always absorbed naturally.—Dr. R. L. BOWLES said that the position of the patient during the administration of the anæsthetic was of very great importance. The sound side should be uppermost. Two cases had been recorded by different observers during the last few weeks in THE LANCET in which death occurred in cases of this kind while an anæsthetic was being given. The patient was turned on his sound side to facilitate the operation; dyspnœa suddenly occurred and the patient died, pus having found its way from the pleural cavity through the bronchi and gravitated into the bronchi of the sound lung.—Dr. WEST, in reply, said that in the cases he had referred to the condition had existed for some time and the

Digitized by Google

symptoms were not urgent. He thought that the moral to be drawn from the result of the operation on Sir Andrew Clark's case was that it should have been performed earlier. He wished to insist that in cases of pleural effusion the lung was not collapsed as often as had been represented and could often be felt to expand when paracentesis was performed.

Dr. SYMONS ECCLES read a paper on the Mechano-therapy of Moveable Kidney. Since the year 1892 twenty-one cases of moveable kidney with local pain and tenderness had come under observation and treatment. Of these, sixteen had been treated by the "rest cure" with special attention to abdominal massage and exercises for periods varying from fourteen days to eight weeks, and of these eight were recorded in detail; seven were lost sight of within four months of treatment. Of these one was a complete failure, out was the only one in which immediate benefit did not follow. Five were greatly improved by abdominal massage, exercises, and the application of a pad and belt; one of these had been free at the present time from all discomfort for five years and another for two years, whereas both had previously suffered from pain and general malaise for prolonged periods. The results obtained in the majority of these cases were so satisfactory that they bore favourable comparison with records of those treated by operation, and in view of certain cases which have occurred there was something left in favour of employing milder means for the relief of nephroptosis than surgical interference involving either nephrorrhaphy or nephrectomy. Early diagnosis, reposition, and the maintenance of the organ in its normal position by methods which also conduce to the improvement of general health would appear to go far towards the relief of a patient from the necessity of having the kidney stitched into its place or removed from the body as the advocates of early operation advised. Sufferers from floating kidney should first be treated by rest, massage, and exercises before they were exposed to risks, which certainly existed, however small they might be rendered by the skill of the operator. The cases for detailed description were selected as typical of the conditions under which nephroptosis occurred in males and females. Most of them were very thin and there was associated ptosis of the stomach and other viscera. As they regained subcutaneous fat the symptoms disappeared and in nearly all the relief was permanent.—The PRESIDENT said that many of the patients in whom a moveable kidney was discovered on palpating the abdomen were quite unaware of the condition, and he thought that it was unwise for the physician to communicate his opinion to the patient as they at once became hypochondriac and the floating kidney became a fixed idea. He thought that it was unusual for marked symptoms to occur if the patient was unaware that his organ was dislocated. If there were severe symptoms Dr. Eccles's plan of treatment offered the least disagreeable way of getting rid of the trouble with which he was acquainted and would be well worth trying.—Dr. DE HAVILLAND HALL said that the patients were not always made neurasthenic by being told the nature of their complaint and mentioned a case in which the converse happened. The patient complained of indefinite abdominal symptoms and was much distressed because none of her advisers could account for them. When told that she had a moveable kidney the mere knowledge that her symptoms were explained gave her so much gratification and so thoroughly set her mind at rest that, although no treatment was adopted beyond the application of a simple pad, her symptoms ceased to be obtrusive and she resumed an active life. — Mr. P. J. FREYER said that he would have liked to have had more details of the mechanical appliances used and of the method of massage employed. He had not seen any cases in which permanent benefit resulted from massage. In one case the patient had been through a severe course of massage before coming to him, but instead of its having favoured the deposit of fat around the kidney he found when operating that there was complete absence of fat.—Dr. ECCLES, in reply, said that he quite agreed with what had been said about keeping the knowledge of the nature of the complaint from the patient. Several of his patients were even now unaware that they had been treated for a moveable kidney. In replacing the kidney the position should be that which many patients instinctively assumed to relieve pain—viz., the patient should lie on the opposite side, flexing the thigh of the same side as the moveable organ acutely on the abdomen and extending the arm of that side above the head.

ÆSCULAPIAN SOCIETY OF LONDON.

Exhibition of Cases and Specimens.—Hypodermic Injection of Cocaine.—Notes on Cases of Traumatic Fracture of the Thigh.—Fatal Secondary Hæmorrhage from the Liver and Perforation of the Gall bladder.

A MEETING of this society was held on Nov. 5th, Dr. B. G. MORISON, President, being in the chair.

Mr. G. ANGUS HUNT showed a man, twenty-seven years of age, who was the subject of Right-sided Enlargement of the Thyroid Gland with marked proptosis and a systolic mitral murmur. The thyroid enlargement had diminished after taking liquor sodii arseniatis in doses increasing up to ten minims three times a day.

The PRESIDENT read a short note on the Hypodermic Injection of Cocaine for the Relief of Pain. The dose employed was one-third of a grain guarded by three minims of liquor strychniæ. He had found this method useful in neuralgia, though generally less effectual than morphia.

Mr. STEPHEN PAGET read notes of the following cases. Case 1. Traumatic Fracture of the Thigh in its Middle Third. A huge extravasation of blood occupied the thigh from the ischium to the knee and the limb was pulseless and distended. The common femoral artery was tied and the thigh was amputated at the hip. A post-mortem examination showed that the superficial femoral artery and its vein were both torn across, the upper and lower ends being widely separated. Case 2. Fatal Secondary Hæmorrhage from the Liver in a boy who had been run over by a van. The primary shock having been recovered from he seemed fairly well. A rise of temperature (103° F.) on the fifth day subsided rapidly. Signs of hæmorrhage appeared on the tenth day and he died. It was afterwards found that the liver was ruptured and extensive effusion of bile had taken place beneath the capsule posteriorly. Case 3. Perforation of the Gall Bladder in a woman, aged sixty-six years, with effusion of bile into the abdominal cavity. The calculi were successfully removed by laparotomy, but the patient succumbed to exhaustion five days later.

The PRESIDENT, for Dr. J. W. HUNT, showed a specimen of Hepatic Abscess. The patient had been invalided home from Brazil on account of diarrhœa which continued to trouble him afterwards. The liver extended as low as the umbilicus. The temperature was never above 100° F. The liver was aspirated on two occasions and a considerable quantity of pus was removed. The abscess subsequently invaded the right lung and proved fatal soon afterwards.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.

A MEETING of this society was held on Nov. 11th, the President, Dr. SINCLAIR WHITE, being in the chair.

Mr. ARCHIBALD YOUNG showed for Mr. PYE-SMITH: (1) an infant with Syphilitic Chancre of the Eyelid; and (2) a large Sarcoma of the Kidney removed by a successful operation.

Mr. SIMEON SNELL introduced the following cases:—Case 1. Double Papillitis following Influenza. The patient was a girl, aged eighteen years. The attack six weeks previously appeared to have been severe and she had been confined to bed for fourteen days. The dimness of sight was noticed whilst she was in bed. Now in each eye the vision equalled $\frac{6}{36}$. Case 2. Conical Cornea in each Eye. The patient, a man, was introduced to illustrate the reflections occasioned by Placido's disc and the exhibitor's disc of radiating lines. Case 3. Embolism of the Central Artery of the Retina. Current was restored by massage. Loss of sight in a middle-aged man occurred suddenly on the 9th inst. at 7 A.M. At 11.30 A.M., when first seen, the retina was bloodless and the arteries were empty. Massage of the globe was adopted and a change in the appearance of the retina was quickly observed. The next day the retinal circulation was apparently re-established; the arteries and veins in all parts carried blood; he could detect fingers.—Mr. SNELL also made some remarks on the Surgical Treatment of High Degrees of Myopia. He had recently operated on eight cases by removal of the crystalline lens. In three instances the patients had undergone operation on both eyes

Digitized by Google

with most satisfactory results. In each case the patient had returned after the first operation and asked to have the other eye treated in a similar manner. The patient shown was an example. To use his own words, he now saw better than he had ever done before. Myopia of 26 D. in the right and 25 D. in the left eye was after operation reduced to 2·5 D. and 2 D. respectively and vision had risen from $\frac{1}{24}$ to $\frac{6}{6}$.

Dr. GRAY NEWTON related and made remarks upon two anomalous cases of Antipyrin Poisoning which had recently occurred in his practice.

Dr. HUNT showed specimens of Aneurysm of the Innominate Artery, Sarcoma of the Lung and Cancer of the Liver, and read notes of the cases.

Dr. WILKINSON demonstrated a striking case of Associated Movements of the Hands.

Mr. PRIESTLEY showed a child with Congenital Absence of certain Toes and of both Fibulæ.

Mr. ARCHIBALD CUFF showed Surgical instruments.

The PRESIDENT, Mr. SNELL, Dr. SWEETEN, Dr. WILKINSON, Dr. MARTIN, Dr. HUSBAND, Dr. ADDISON, Dr. WADDY, and Dr. BURGESS made remarks on the specimens and cases.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

President's Address.

A MEETING of this society was held on Nov. 3rd, Dr. CATTLE, President, being in the chair.

The PRESIDENT delivered an address on Medicine during the past Twenty-five Years. He said the great leading characteristic of medicine during this period was its advance by means of the experimental method. The discovery of the antiseptic treatment and the rapid progress of bacteriology were noticed at length. In the injection of the serum of immunised animals it seemed as if there had been found a method full of hope in the treatment of diphtheria and other infective diseases. The discovery of the nature of myxœdema and its treatment by means of thyroid extract had been a brilliant piece of scientific and practical work. The effects of extracts of the other ductless glands were undergoing investigation. The greatest number of new drugs belonged to the classes of hypnotics and antipyretics, but very few of these were of first importance. The tendency to prescribe alcohol in the treatment of disease was certainly declining. In the definition of disease the greatest progress had been made in the differentiation of diseases of the nervous system. The progress in all branches of surgery had been most remarkable, but chiefly in regard to the cavities of the head, the spine, and the abdomen. The modern knowledge of extra-uterine gestation and its relations with pelvic hæmatocele was one of the greatest results of abdominal surgery. Cerebral and spinal tumours and abscesses were not only better diagnosed but could now be cured by surgical interference.

A vote of thanks, proposed by Dr. W. RANSOM and seconded by Dr. POWELL, was carried unanimously.

Infantile Cerebral Degeneration.

A meeting was held on Nov. 17th, Dr. CATTLE, President, being in the chair.

Dr. E. C. KINGDON and Dr. J. S. RISIEN RUSSELL brought forward a paper illustrated by lantern slides on Infantile Cerebral Degeneration with Symmetrical Changes at the Macula. The disease was stated to be rare and often attacked more than one member of the family. Commencing in the early months of infant life by muscular enfeeblement, especially of the neck and back, it progresses to almost complete paralysis and terminates in the death of the patient about the end of the second year. The ophthalmoscopic appearances which are seen early in the disease and persist unchanged during the remainder of life consist of a whitish-grey patch at each macula with a red centre; later optic atrophy supervenes. Microscopic examination of the brain and spinal cord in two cases of the four seen by Dr. Kingdon and Dr. Russell showed marked degeneration of the large pyramidal cells of the cortex of the whole brain with descending degeneration of the cord.

EDINBURGH OBSTETRICAL SOCIETY.

Valedictory Address on the History of Ovariotomy and the Law of Professional Secrecy.—Natural Parturition.—Election of Officers.

A MEETING of this society was held on Nov. 10th, Dr. ALEXANDER BALLANTYNE, the retiring President, being in the chair.

Dr. BALLANTYNE gave his Valedictory Address and referred to the loss the society had sustained by the death of several corresponding and ordinary Fellows, among whom was Dr. George Battey, of Georgia. The extirpation of the ovaries for otherwise incurable disease apparently suggested itself to his mind after the prolonged study of a case of amenorrhœa from absence of the uterus with intense suffering at the menstrual periods, ultimately exhausting the patient and causing death. Hence he conceived the idea that by removing the ovaries he would produce an artificial menopause and by its production relieve or cure the patient. In August, 1872, Dr. Battey removed both ovaries successfully by abdominal section with the result of complete restoration to health. Others established the safety and utility of the operation beyond a doubt. Perhaps now ovaries are removed on comparatively slender pretexts but Dr. Battey emphatically stated that it should only be done as a last resort. "This much," he says, "is due to the dignity of our calling; this much is due to humanity, to decency, and to public morality." In referring to the death of Sir Spencer Wells Dr. Ballantyne gave some account of the development of ovariotomy. A series of cases had been operated upon by the "Father of Ovariotomy," Ephraim McDowell, in the early part of the century. Clay in England began in 1842, and the two Atlees in America—John in 1843 and his more famous brother Washington in 1844. These had continued in the face of all opposition and fought for the existence of the operation before the time Wells began to operate. The American writer Parslee in 1872 stated that of the first three the credit belongs to Clay of having placed the operation of ovariotomy upon a sure foundation. Two years before Wells began Clay had performed the operation 71 times with 75 per cent. of recoveries in his last 31 cases. With this average he ended his career as an ovariotomist after performing the operation 400 times. In 1854 Wells, previously an assistant surgeon in the Royal Navy, was appointed to the Samaritan Hospital and had assisted Baker Brown in his eighth case of ovariotomy. When the Crimean war broke out he was attached to the army and there learned "that a man's abdominal walls might be lacerated with fragments of shell, his intestines protruding and covered with mud, so remaining for several hours, and yet after careful cleansing and accurate closure of the wounds complete recovery was possible." This made him much less afraid of abdominal wounds. This probably led him to visit Clay at Manchester and to be present at one of his operations. He made many inquiries and subsequently corresponded about the operation. He began an operation at the end of 1857, but was apparently dissuaded from going on with it by Baker Brown. In February, 1858, he completed his first ovariotomy. He had plentiful material in London, had the whole field to himself, and was well-known to a professional circle. Like most epoch-making men he was energetic, decided, and combative, ready to grapple with difficulty and to meet opposition. He invited spectators and courted criticism; everything he acquired from observation or got from others he used for perfecting his results. His early cases were not more successful than the early cases of Clay, yet such publicity did he give them and with such power did he advocate the claims of the operation that he compelled men to listen and converted them to his views. It was this rather than any exceptional brilliancy of operating or its results that carried him to the foremost rank of ovariotomists and made him even more than Clay the great apostle of ovariotomy. In his first 150 cases he had 47 deaths. It was, however, for Keith to verify "that this long-despised operation is now the safest of all the great surgical operations." He began in 1866, and in his first 48 cases had only 11 deaths, a result which in some measure prepared the profession for the astounding record of 73 ovariotomies without a death and 97 recoveries out of 100. This attested his marvellous skill as an operator and made his results, according to Sims,

Digitized by Google

"the wonder and admiration of surgeons all over the world." In referring to one of the meetings held *in camerâ* Dr. Ballantyne discussed the relation of obstetricians and gynæcologists to the law chiefly on the question of professional secrecy. Theoretically, of course, the medical man is constantly under the Hippocratic oath—that facts, medical or otherwise, which he learns from his patient during professional attendance should not be divulged, and the law of this country seems clearly to hold that a secret acquired by a medical man during his attendance upon a patient is the secret of the patient, and therefore that she has a *primâ-facie* right in law to require that her secret should be kept unless it can be shown that there is some paramount reason setting aside that right. The law then so far upholds our old professional rule. Some judges have gone further and have indicated that medical men should *legally* be under this ancient rule with certain exceptions. Thus Judge Buller expressed his regret that the information got from medical men was not privileged. Lord Brougham expressed himself in much the same way, and Chief Justice Best said that the law was hard in itself, of questionable policy, and contrary to that of America and France; while Justice Hawkins in the comparatively recent case of Kitson *v.* Playfair and wife said that there were criminal cases, and he instanced one—that of self-inflicted criminal abortion—where it would be "monstrous cruelty" for the medical man to inform the police; and with regard to those when it was said the medical man should inform the judge might himself in some cases refuse to commit a medical man for contempt in refusing to reveal confidences. The practitioner is therefore evidently in a position of serious doubt. In America and France the law differs from that of this country in so far that it binds the medical man to keep his patient's secret. In America the law binds the professions of the Church, law, and medicine equally. According to this code "the clergyman is prevented from disclosing confessions made to him in his professional character in the course of discipline enjoined by the rules of practice of the religious body to which he belongs. The attorney or counsellor-at-law is not allowed to disclose a communication made by his client to him or his advice given thereon in the course of his professional employment. And a person qualified to practise physic or surgery is not allowed to disclose any information which he acquired in attending a patient in a professional capacity and which was necessary to enable him to act in that capacity." This law recognises that the community needs help for its suffering from these three professions and that it would be wrong to put any obstacle in the way of obtaining it whether guilty or innocent. The revisers of the American law went further by stating that the necessity of the law is even stronger in the case of medical men than with legal advisers. But this law is broken in its administration. Thus Judge Bartlett speaking on the subject of criminal abortion at a meeting of a medical society said: "The rule may be regarded as pretty well settled in this state that the physician is compelled by law to disclose (in the witness box, not voluntarily) what he knows indicating the commission of criminal abortion where the victim of that abortion is dead. Where the patient, however, survives and does not waive her privilege the medical practitioner must keep silent." District-Attorney Backus at the same meeting gave the opinion that a self-attempted abortion should not be disclosed whether the person lived or died, but where it is done by another the medical man should endeavour to procure the consent of the patient to inform even though she survives. In this country the medical man is not privileged, and this opinion has been again confirmed by the answer of counsel to the question of the Royal College of Physicians of London, "Has a medical practitioner any privilege with regard to secrets confided to him in the course of his practice analogous to the privilege as between a solicitor and client or otherwise?" Answer: "We are of opinion that there is no privilege attaching to statements made to a medical practitioner by his patient." Yet we know that should a medical practitioner disclose any fact to a third party which may affect the character of, or cause injury to, the patient he would be liable to an action for defamation of character. In cases of concealment of pregnancy the presumption is that the medical practitioner should inform, and yet why should the law or we be less careful to protect a poor woman who, in the agonies of labour and great distress of mind, allows her child to die than she who has destroyed her child in utero? Then in those cases of pregnancy with abortion in women out of wedlock, or where the wife has been separated for some time, here it is most necessary for the medical man to keep silent in the interest of the patient and for his own protection. Again, in the case of servants about whom the employer is suspicious and thus has sent for the practitioner to tell what is the matter, it has been said that the medical man is the agent of the employer and receives his fee from her and therefore must divulge the condition. But according to law the medical man must have the full permission of the patient to see and prescribe for her and also her permission to tell her employer what she suffers from. In the case of gonorrhœa and syphilis it must not always be taken for granted that a married woman has obtained the disease from her husband, and if not so it would be wrong to expose him to the risk just as much as when the husband is suffering from such a complaint we protect the wife. It is also very difficult to know how to act when such diseases occur in servants and employés, as in these cases the medical man runs the risk of an action at law. In obstetrics the opinion of counsel is "that the law does not forbid the procurement of abortion during pregnancy or the destruction of the child during labour where such destruction is necessary to save the mother." But this is only the opinion of counsel—the law remains; and though the illegality of these operations may not be entertained in the law courts, still "in the event of the death of the mother the medical man exposes himself to a prosecution for a criminal offence." Why, then, should the law not be amended to run as it does in the penal code of the State of New York? "A person who with intent thereby to procure the miscarriage of a woman, unless the same is necessary to preserve the life of the woman or of the child with whom she is pregnant, is guilty of abortion," &c. The alteration of our law should be made a matter for serious consideration; the law should emphasise in a decided way a patient's legal right of privileges which she only can waive except in certain cases and these the law should carefully define.

The SECRETARY, on behalf of Dr. C. F. PONDER, of Kalimpong, read a paper on Natural Parturition with a description of a new instrument the Vector.

The following office-bearers were elected for the ensuing session: — President: Dr. J. Halliday Croom. Vice-Presidents—Senior: Dr. R. Milne Murray; Junior: Dr. N. T. Brewis. Treasurer: Dr. W. Craig. Secretaries: Dr. J. Haig Ferguson and Dr. W. Fordyce. Librarian: Dr. R. Milne Murray. Editor of Transactions: Dr. J. W. Ballantyne. Members of Council: Dr. J. B. Buist, Dr. W. N. Elder, Dr. J. R. Hamilton (Hawick), Dr. Fraser Wright, Professor A. R. Simpson, Dr. Melville Dunlop, Dr. F. W. N. Haultain, and Dr. Alexander Ballantyne (Dalkeith).

BIRKENHEAD MEDICAL SOCIETY. — The first meeting of the current session was held on Nov. 12th, Dr. R. Sydney Marsden, President, in the chair. Mr. Wm. Dalzell, M.A., M.B., C.M. Edin., was elected a member of the society. The President delivered the inaugural address, entitled, "Preventive Medicine in Relation to the Psychical and Hereditary Elements in Disease." Dr. A. C. E Harris, J.P., moved, and Dr. James Lambert seconded, a vote of thanks to the President for his address. Dr. Marsden replied, and the society adjourned. There was a large attendance of members.

UNIVERSITY COLLEGE, BRISTOL.—The annual meeting of the Governors of University College, Bristol, was held on Nov. 17th under the presidency of the Bishop of Hereford. The report alluded to the loss which the College had sustained by the death of Professor Greig Smith and recorded their appreciation of his able services in the medical department. Professor J. E. Shaw has been appointed a representative of the Faculty of Medicine upon the council. There were 583 students during the session, an increase of 60 over the previous year. The financial statement showed that the total expenditure of the College was £6290 and the income £5272, leaving a deficiency of £1018.—The Company of Cloth workers have offered to contribute the sum of £100 per annum towards the funds of the College for a further period of five years.—In addition to the Science Scholarship of the annual value of £150, given by H.M. Commissioners, tenable for two years, Mr. George Brebner has given a botanical research scholarship of £20 per annum and the Bristol Chamber of Commerce one of the value of £20 for the encouragement of the study of the metric system. An engineering works' scholarship has also been offered.

Reviews and Notices of Books.

The Practitioner's Handbook of Treatment. By the late J. MILNER FOTHERGILL, M.D., M.R.C.P. Fourth edition. Edited and in great part re-written by WILLIAM MURRELL, M.D. Brux., F.R.C.P. Lond., Physician to and Lecturer on Pharmacology and Therapeutics at the Westminster Hospital. London: Macmillan and Co. 1897. Pp. 683. Price 15*s*.

THE first edition of this work appeared in 1876 and in its three editions was well known throughout the whole medical world. In bringing out a fourth edition Dr. Murrell has retained very successfully Dr. Fothergill's original design and his characteristic style, although the enormous progress in all departments of medicine during the ten years that have elapsed since the third edition was published has necessitated considerable additions and a thorough revision of the work. This is well shown in the first chapter, where an interesting review of the more recent advances in the methods of treatment and diagnosis will be found.

The first subject considered is Assimilation, and under this head we find the physiology of food and digestion considered in so far as is necessary for the complete comprehension of the *rationale* of therapeutic measures. Amongst other classes of drugs hæmatinics receive a large share of attention, and we would especially draw the reader's notice to the remarks on the administration of iron, which is regarded as "rather a food than as a medicine." Chapter III. deals with Excretion. The portion devoted to physiology is here again well worth perusal teeming as it is with therapeutic hints. In this chapter uræmia and its treatment are considered, the compensatory action of organs are pointed out, and an important class of drugs is described, the alteratives. "Their action may be silent and imperceptible, their mode of influence may be unknown, but their therapeutic effects are among the most assured of clinical facts." In Chapter IV. Body Heat and Fever are discussed and we naturally find described the effects of high temperature on tissues and on the brain, and the various means for reducing temperatures. Inflammation and its varieties are described in Chapter V., and Anæmia, Plethora, and Congestion in Chapter VI.

Growth and Decay form an interesting section, Dr. Fothergill's charming style of writing being particularly noticeable in the paragraphs on Decay, and the indications for treatment in the ailments of advanced life.

There may be found some who will not altogether agree with the remarks found in Chapter VIII. — Abnormal Growths; some of the expressions used may at first sound strange, but further thought will show that there is much sound reasoning in them. For instance, in speaking of tubercle the following sentence is employed: "The greatest danger for the majority of consumptives is that they are apt to become tuberculous," the meaning of which is that although the writer fully acknowledges the tubercle bacillus as an essential part of the tuberculous process, yet there is a second etiological factor with which as yet we are imperfectly acquainted. Chapter IX. deals with Blood Poisons and Specific Poisons—namely, septicæmia, sapræmia, pyæmia, and the specific fevers. This section is quite up to date, all the more recent scientific discoveries being introduced. Acute and Chronic Disease is the subject of the next chapter, giving, amongst other forms requiring treatment, those of hæmorrhage, syncope, and asphyxia. The theory of stimulants also receives considerable attention. In Chapter XI. the treatment of Diabetes, Rheumatism, and Gout is found. The remarks on diabetes are particularly instructive. The matter of diet is shown to be all important, but the writer sounds a warning note against too rigid rules. "The dietary of diabetic patients is not to be laid down by rule of thumb. If the patient wastes on any dietary, then that dietary should be altered. Wasting is the index for treatment rather than the amount of sugar in the urine."

"Great importance has ever been attached to that acquaintance with families and individuals which is summed up as 'knowing their constitution.'" Such are the opening words of the chapter on Diatheses and Cachexiæ, in which much interesting reading will be found. Action and Inaction is the heading of the next chapter and the various forms of narcotics occupy its greater portion. Chapter XIV. deals with the various methods employed in the treatment of disorders of the Circulatory System, and Chapter XV. with those of the Respiratory System, but this latter seems to us to scarcely reach the high standard of the rest of the work. The treatment of Disorders of the Digestive System, however, is excellently set forth and will be read with advantage both by practitioners and students. We consider Chapter XVII., on the Urinary System, one of the best in the book, the remarks on albuminuria and chronic renal changes being especially noteworthy. Chapters XVIII. and XIX. deal with the Reproductive System and the Cutaneous System respectively. The Lymphatic and Nervous Systems are considered subsequently.

The remaining chapters are devoted to Public and Private Hygiene, Food in Health and in Ill-health, the Dietary in Acute Disease and Mal-assimilation, the Management of Convalescence, and finally, the Medical Man at the Bedside. The last named we strongly recommend to the notice of the young practitioner. In it he will find most useful hints as to the management of patients as indlviduals, instruction on which point is so often neglected in the ordinary curriculum. Taking the book as a whole we cordially recommend its perusal to the student and busy practitioner, to the one as a text-book and to the other as a work of reference.

A Treatise on Obstetrics for Students and Practitioners. By EDWARD E. DAVIS, A.M., M.D., Professor of Obstetrics and Diseases of Infancy in the Philadelphia Polyclinic, &c. Illustrated with 217 Engravings and 30 Plates in colours and monochrome. Edinburgh and London: Young J. Pentland. 1897.

THE author's aim in preparing the volume before us has been "to furnish to the student a text-book and to the practitioner a work of reference in which both the science and the art of obstetrics should be fully set forth in accordance with the most modern results of investigation and experience." We think that on the whole the author has succeeded in accomplishing his purpose. On the all-important subject of antiseptics nothing could be better than the following direction for disinfecting the hands prior to making a vaginal examination: "The attendant must scrub his hands thoroughly with soap and hot water, using a nailbrush; then rinse them thoroughly in hot water, and then scrub them in bichloride of mercury solution 1 in 1000." We quite agree, too, with the author's view that "no lubricant is required in normal cases for the finger, for the increased secretion of mucus renders this unnecessary." We notice that in describing normal labour, speaking of the removal of the placenta, he says, "It may then be grasped by the fingers and gently removed, care being taken not to tear the membranes." But we see no direction to twist the membranes into a rope which is a precaution usually adopted to attain the end in view. Curiously, there appears to be no mention of accidental hæmorrhage under that name either in the chapter on Hæmorrhage or in the Index; concealed hæmorrhage is described, also post-partum hæmorrhage and hæmorrhage due

Digitized by Google

to placenta prævia, in one chapter. We think that students would have a clearer idea of the matter if these hæmorrhages were described in separate sections. As regards the treatment of post-partum hæmorrhage, which is for the most part clearly given, we think the statement that "the uterine and ovarian arteries may also be ligated by abdominal section, followed by hysterectomy at the junction of the fundus and cervix" should for the benefit of the student be qualified by saying that such a measure can hardly ever be necessary, as we venture to think there is no obstetrician of eminence in this country who has ever found it requisite to perform the operation. There are many good illustrations, the least successful from the point of view of teaching being, as usual in matters of the kind, those derived from actual photographs. Thus on p. 226 there is a photograph showing the patient's buttocks and the shirtsleeves and hands of the obstetrician and his assistant the inspection of which, in our opinion, really teaches nothing. There is a section on Infancy in Health and Disease and one on the Jurisprudence of Obstetrics; there is also a good account of Symphysiotomy. The work is well worthy of careful perusal.

Ringworm and Alopecia Areata: their Pathology, Diagnosis, and Treatment. By H. ALDERSMITH, M.B Lond., F.R.C.S. Fourth edition. London: H. K. Lewis. 1897. Price 10*s.* 6*d.*

THIS edition, the author tells us, has been re-written, but unfortunately it has also been enlarged by one-half as much again as the third edition, and now forms an octavo volume of 327 pages. Although no doubt the researches of Sabouraud and those who have worked on the same lines required that the work should be recast the subject scarcely necessitated so much enlargement, and in future editions by compression and avoiding repetitions which are somewhat numerous a reduction in the amount of print could easily be made without sacrificing valuable matter. The work contains a clear and succinct account of the new observations on the plurality of the fungi which produce the clinical groups of affections classed under the term "ringworm," and the author sets forth impartially the views of others and shows how far Sabouraud's work has been confirmed by the English workers—Adamson, Fox and Blaxall, Leslie Roberts, &c.—and in what points his deductions must be refuted or modified. Much work has also been done in Germany and Italy on the subject, but of this we do not hear from the author; his own views, however, founded on clinical and microscopical observations are rightly and clearly given.

On various points of treatment Dr. Aldersmith's wide experience enables him to speak with authority, and his trials of the latest specifics will save others from wasting valuable time in going over the same ground. Thus of formalin he tells us that in three-fourths of the cases in which he has used it he has had to give it up either from its being a failure after from six to nine applications or because the parents would not allow it to be continued on account of the pain produced by it. He justly remarks that more rapid cures are not to be expected from new parasiticides, but from improved methods of their application.

On the subject of Alopecia Areata the author is strongly in favour of a neurotic theory to explain all the cases, a view which is losing rather than gaining ground. He quotes freely, however, from authors on both sides. We must protest against his frequent use of the generic term "alopecia" for baldness from all causes as if it were synonymous with "alopecia areata." Possibly this may be due only to carelessness but it is an inaccuracy which should be avoided.

Whilst dermatologists will not find in the work information with which they are not already familiar those who are less expert may rely upon its being a clear and readable exposition of the present knowledge of the subject. The new illustrations and other portions of the publisher's task are well done.

LIBRARY TABLE.

St. Thomas's Hospital Reports. New Series. Edited by Dr. T. D. ACLAND and Mr. BERNARD PITTS. Vol. XXIV. London: J. & A. Churchill. 1897. Price 8*s.* 6*d.*—We are pleased to see the reports of this large hospital, as these volumes always contain much of interest to the profession. The first part of this volume which consists of papers on various subjects is perhaps less full than usual; we miss the names of many who generally supply contributions. There are, however, some papers which will repay perusal and be useful for reference. Amongst these we may mention one by Mr. Makins on Three Cases of Injury to the Abdominal Viscera; on Treatment of Fracture of the Patella (both early and late) by Operation, by Mr. H. H. Clutton; on Some of the Rarer Forms of Tuberculous Disease of the Knee-joint, by Mr. H. B. Robinson; on the Displacements which occur after Tuberculous Disease of the Knee-joint in Children, by Mr. T. H. Kellock; and on the Occurrence of Relapse in the Specific Fevers, by Dr. F. F. Caiger. There are also contributions from Dr. F. R. Walters, on Osteo-arthropathy and its Relationships, and a Case of Hyperplastic Osteo-arthritis or Pulmonary Hypertrophic Osteo-arthropathy of Marie; and another one from Dr. Cory—Notes on the Examination of the Bodies of Fifty-eight Children Born Dead or Shortly Dying (third series). A reprint is also made of a paper by the late George Rainey on the Artificial Production of Certain Organic Forms and the Manner in which they are Produced, and to this there is an introduction by Mr. W. W. Wagstaffe. There is much valuable information in the carefully compiled medical report for which Dr. C. R. Box is responsible, especially in the tables appended to the body of the report. During the year 1895, the antitoxin treatment of diphtheria was adopted in every case and was commenced immediately after admission. The result is shown as follows: 111 patients of all ages show a mortality of 23·42 per cent. In 1894 the mortality-rate of the cases not treated with antitoxin was 40·56 per cent. and the average rate of mortality for the ten years preceding 1895 equalled 49·8 per. cent., whilst the percentage requiring tracheotomy was 87·93 in 1895 and 91·37 in 1894—of these the percentage of deaths was 37·25 in 1895 and 66·03 in 1894. Another point which is brought out by these tables is that the diminution of mortality in 1895 was accompanied by a considerable increase in the incidence of complications—albuminuria, nephritis, paralysis, and broncho-pneumonia. There were 64 cases of typhoid fever under treatment with a mortality of 12·5 per cent., the deaths being the result of exhaustion and cardiac failure in seven out of the eight cases. The surgical report, written by Mr. C. S. Wallace, shows also proofs of careful compilation. We are struck with the amount of space devoted to a consideration of cases of disease of the digestive tract in the special tables. They are, however, interesting and their value amply compensates for the amount of space taken up, more especially as the table of radical cure of hernia no longer appears. The other reports are as follows: that of the Obstetrical Department, by Dr. Cory; of the In-patient Department for Diseases of Women, by Dr. W. H. Tate; of the Ophthalmic Department, by Mr. H. G. Toombs; of the Department for Diseases of the Skin, by Mr. A. H. Payan Dawnay; of the Department for Diseases of the Throat, by Mr. Stabb; and of the Electrical Department, by Dr. H. G. Turney.

The Nurse's Handbook of Cookery. By E. M. WORSNOP, assisted by M. C. BLAIR. London: Adam and Charles Black. 1897. Pp. 108. Price 1*s.* 6*d.*—In this little work there will be found plain and clear directions for the

Digitized by Google

preparation of a great variety of foods suitable for both sick persons and convalescents, the dishes varying from beef-tea, mutton-tea, and peptonised articles, to such delicacies as roast pheasants, baked sweetbreads, boiled tongue, omelettes, &c. There is an introduction in which the ability of the author is vouched for by the superintendent of cookery to the London School Board.

The Surgical Diseases of Children. By EDMUND OWEN, M.B. Lond., F.R.C.S. Eng., Senior Surgeon to the Hospital for Sick Children, Great Ormond-street; Senior Surgeon to, and Lecturer on Surgery at, St. Mary's Hospital, London. Illustrated with 5 Chromo-lithographs and 120 Engravings. Third Edition, revised and enlarged. London, Paris, and Melbourne: Cassell and Co. 1897. Pp. 504 Price 21*s.*—This new edition is an improvement in several ways on the first and second editions, and in its present state the work is a good introduction to the study of surgical diseases as they appear in children; but it is not, and is probably not intended to be, a complete treatise on the surgery of childhood. In the description of the treatment of a case of diphtheria we find the following sentences: "The fumes of burning sulphur with steam are the best general disinfectant for rooms and clothing. Indeed, the periodical burning of sulphur in the sick-room is expedient; children are but little irritated by the fumes." From the first half of this extract we do not dissent, but the second half is surely erroneous. Will sulphurous fumes which do not irritate the child prove very destructive to the bacillus diphtheriæ? The practice can have no real value and is on a par with the popular custom of placing in the sick-room saucers containing Condy's fluid. With Mr. Owen's remarks on craniotomy for microcephalic idiots we cordially agree. The operation was, indeed, a failure; in many cases it was rapidly fatal, and in those in which the patient survived the operation the mental improvement was extremely doubtful. A very good skiagram is given of a tuberculous hip (p. 424); it was taken by Dr. Macintyre, of Glasgow.

JOURNALS.

Heilstätten-Korrespondenz (Sanatorium News). Organ of the German Central Committee for the Providing of Establishments for the Treatment of Diseases of the Lungs. Under the direction of Dr. GOTTHOLD PANNWITZ, Business Manager of the Central Committee. No. 2. Berlin, Nov. 1st, 1897. First year of publication.—The following is from the current number of this journal: "Ever-widening circles take a lively interest in the systematic struggle against phthisis as it is carried on in Germany by the providing of adequate sanatoria for pulmonary cases, more particularly in connexion with institutions for invalids and for the insurance of old age pensions. In order to make the experience that has been gained in this department accessible to the public at large as well as in order to obtain due appreciation of the literature that has been collected on the subject the German Central Committee for the providing of Establishments for the Treatment of Diseases of the Lungs has determined to issue a *Heilstätten-Korrespondenz (Sanatorium News)*, reprints from which are on request willingly sent to newspaper offices free of charge. Application should be made to the business manager, 19 and 20, Klopstockstrasse, Berlin, N.W."

The Journal of Balneology and Climatology. Vol. I., Part 4. London: John Bale, Sons, and Danielsson, Limited. Price 2*s.*—This part marks the completion of the first volume of the official journal of the British Balneological and Climatological Society, a society which is doing good work in calling attention to our own health resorts, in furthering their improvement, and in establishing intercommunication between British medical men generally and the practitioners who reside at the various British health resorts. "The Climate of the Dwelling House," by Dr. Poore, sounds a very necessary note of warning as to the futility of sending persons abroad to climates other than their own where, although the right conditions as to altitude, soil, sunlight, temperature, humidity, &c., may prevail, the air is impure. In this case "climatic treatment becomes a solemn and expensive farce." "Which of us," says Dr. Poore, "has not experienced the pleasure after a long day's tramp of descending through some valley of exquisite beauty to the village containing the hotel which is to afford dinner and a night's rest? We see our earthly paradise nestling far below—a dream of loveliness—but 'tis distance lends enchantment to the view,' and arrived at our destination the eyes have been quickly disillusioned by the nose." Pure air is, we know, an important factor in health, and an active cause in producing impurity is overcrowding whether in cities, towns, or individual places of residence. Hotels are especially liable to this cause, and in addition the elaborate decorations of the interiors in many cases while pleasing to the eye act as dust traps which accumulate germs of all kinds. Dr. Poore instances the mediæval colleges as seen at Oxford and Cambridge as excellent models which the modern hotel architect might adopt. "They have as a rule ample curtilage, the public rooms are big and often in a building distinct from the living rooms, while the living rooms are quiet and connected with the public rooms by cloisters and covered ways." The article concludes with a plea for better food for invalids at some of the table d'hôtes. "In many hotels, especially in cheap 'pensions,' the feeding is execrable. It is meretricious rather than nutritious, and consists of dabs of disguised garbage to which absurd names are given by ignorant 'chefs' whose only knowledge of cooking consists of opening 'tins.'" Dr. Prosser James contributes an academic paper on the Earliest Recorded Discovery of Thermal Springs. Articles on Helouan-les-Bains, on the Claims of British Resorts with some remarks on Malvern as a Health Resort, and on the Royal Baths at Harrogate will be perused with interest.

Scottish Medical and Surgical Journal.—Four of the articles this month are highly instructive clinical records—namely, the contributions by Dr. Alexander Patterson (Glasgow), on Surgical Reminiscences, including Eighteen Years' Work in the Western Infirmary; by Dr. Byrom Bramwell (Edinburgh), on Cerebral Cases of Unusual Interest; by Dr. A. H. Freeland Barbour (Edinburgh), on Vaginal Hysterectomy by Doyen's Method, with Six Successful Cases; and by Dr. James Carmichael (Edinburgh), on Basal Meningitis. Dr. J. A. Kynoch (Dundee) describes a case of Tuberculosis of the Placenta, and Dr. J. W. Ballantyne writes on Transposition of the Viscera and collects the literature on the subject from 1894 to 1897 inclusive.

Edinburgh Medical Journal.—The opening paper deals with the Hepatic Complications of Typhoid Fever, the author being Professor William Osler, of Johns Hopkins University, Baltimore. The complications described are focal neuroses, jaundice, abscess, the presence of typhoid bacilli in the gall-bladder, the occurrence of acute cholecystitis and cholangitis, and the relation of typhoid fever to gall-stones. He records a case in which Eberth's bacillus was found at a cholecystotomy, although there were no symptoms of typhoid fever. Mr. W. Roger Williams brings forward arguments against the view that cancer is a "morbus miseriæ." The "Medico-legal Notes," by Mr. H. Nelson Hardy and Mr. F. W. Lowndes, contain much salutary advice in reference to the examination of unwilling persons, especially in cases of suspected pregnancy. Altogether there are nine original articles.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 27, 1897.

THE General Medical Council has done one very considerable piece of business during the session which commenced last Tuesday. It resolved with practical unanimity to make a departure in the statement of its objections to the employment of unqualified assistants. The departure consisted in stating clearly that henceforth the employment of an unqualified assistant, except in the form of a pupil, will be apt to be considered by the Council as "infamous conduct in a professional respect," to be punished by removal from the Register. Perhaps a little more time might have been given with advantage to the shape in which the future intentions of the Council were announced and to making clearer the precise nature of the offence which it is proposed in the future to regard so seriously. The language of the new notice makes of it an amplification of the resolutions passed on several occasions already by the Council in condemnation of the employment of unqualified assistants, and it practically makes it an offence to use the services of any unqualified person save such as may be rendered by a pupil to a general practitioner or in a hospital by dressers and clerks to the members of the senior or junior staffs. But the position of the pupil towards the general practitioner is different to his position towards the hospital officer. In the view of the General Medical Council, a body made up predominantly of medical teachers and examiners or of gentlemen representing the teaching and examining bodies of the profession, a general practitioner can only be allowed to have as assistant a pupil for a period of six months in the last or fifth year of his medical curriculum. A junior student is not eligible to assist the general practitioner, nor is the senior student eligible, we suppose, for a longer period than six months. These restrictions may be taken to reflect upon teachers and examiners as much as upon the general practitioner, for they would seem to imply that those who teach and examine medical men have but a small faith in their work, so that they cannot trust (except in a very limited manner) their former charges to transmit to others the lessons they have learnt. Be this as it may, it is not clear from the language of the Council whether a medical man will be allowed to keep a pupil for a longer period than six months without incurring the risk of employing an unqualified assistant.

We do not labour this point for it is quite clear that abuse might arise—nay, it is well known that it has arisen—from the employment of senior students as assistants, but the position of the Council requires exact definition in the interest of employer and employé alike, and this brings us to a point that will be likely, judging from the discussion in the Council, to influence the Council in ...nating whether a person employed by a registered practitioner in connexion with his professional practice is an assistant or a pupil. It seems that if the principal pays, the individual employed will be apt to be regarded as an unqualified assistant; while if the payment is the other way round, he will be regarded as a *bonâ fide* pupil. This is a question which is not settled by the language of the Council and which we would urge must and should be settled. For if such points are left in dubiety the profession will be harassed on a large scale by prosecutions which will often end in failure and the funds of the Council will be drained to no purpose. We are no apologists for the employment of unqualified assistants—we are too well aware of the evil that has in some places arisen in this way—but the practice is too old and has been too much connived at by the General Medical Council for it to be abolished with a stroke of the pen. In particular is it necessary that the stroke be unmistakable in meaning. The past action of the Council has only touched the surface of the evil. It has had reference to gross covering or gross misuse of unqualified assistants. The practitioners offending or found guilty of "infamous conduct" for such offences have been comparatively few; probably not fifty in all. The offence created by the action of the Council this week is practised by hundreds of medical men, probably by thousands. Before a sense of ill-doing can be effectually brought home to them the intentions of the Council must be stated with much more detail and precision than as yet they have been.

Of the main decision of the Council we entirely approve. It is a complete anachronism that half or a third of the work of the medical profession should be done by persons who are not in any sense of the word medical practitioners. Such an arrangement is deceptive as regards the public who think they are getting the advice of qualified persons, and it is grossly unjust towards young practitioners who should find their first and most valuable work in the field of private practice under the supervision of an intelligent and experienced principal. The General Medical Council is doing its duty by legislating for the suppression of all inferior and unqualified forms of practice and all who have the interests of the medical profession at heart will recognise this and applaud its action. But we would beg the Council to make its views very clear indeed, otherwise not only will much irritation be caused but actual injustice will be done.

THE mere mention of the Muzzling Order at the present time seems to excite general attention and bring out a variety of suggestions, so that when the subject was alluded to before a political meeting by the Right Hon. WALTER LONG, who holds the important and responsible post of Minister of Agriculture, it was to be expected that the daily press and the public would freely comment upon his words. Both have done so and the views elicited have been many and divergent, but there can be only one opinion for sensible citizens as to the value of the Muzzling Order as a whole, however open certain details in its working may be to criticism. In the course of his speech before a Conservative meeting at Bournemouth last week Mr. LONG mentioned certain facts which prove incontestably the beneficial effect which has

Digitized by Google

already followed the measures recently adopted for the stamping-out of rabies. The right honourable gentleman stated that in Lancashire and the West Riding of Yorkshire there were 446 outbreaks for the year ending Nov. 19th, 1894, whilst during the same time in 1897 (when the Muzzling Order was in force) there were only 37; of these 24 were in the early part of the year, as since July the West Riding had been quite free and Lancashire had only reported 3 cases. These figures tally with London figures. In London, for the year ending Nov. 15th, 1896, there were 161 outbreaks, and during the same period of time this year, since the Order has been in force, there have been only 29; in fact, only one outbreak has occurred since August. In the Midland district only 6 cases were reported this year, as against 34 during 1896. In the whole of England the number of cases in 1895 was 608, whereas this year they have been reduced to 141. Again, the Board of Agriculture statistics for the week ending Nov. 13th, 1897, show that not a single outbreak was recorded. These facts speak for themselves, and we seem at the present time to be nearer the desired object of getting rid of rabies than we have been for many years. It is to be hoped that the adverse opinions uttered by the dog-loving public will not in any way influence Mr. LONG in his determination to free us from the risks of such a terrible disease.

Under the intermittent muzzling system there can be no doubt that we should never have got rid of the disease, while as far as the dogs themselves were concerned the objections to the wearing of a muzzle were more marked than they are under present regulations. For under the intermittent system just as the animals had adapted themselves to their altered circumstances the Order was removed and freedom restored; but in a few weeks a fresh outbreak of rabies would cause the re-enforcement of the Order and the dogs would again have to undergo the ordeal of becoming accustomed to their restraint. Intermittent muzzling can only end in failure, and it seems incredible that the lesson has never been learnt before. The rigorous application of the muzzle to a wide area around an infected district, or better still to the whole of Great Britain, for a period of not less than twelve months and stringent rules regarding quarantine and supervision of all imported dogs are the only means by which success can hope to be attained. Having once freed the country it would be necessary that the rules regarding quarantine and supervision of imported animals should be strictly adhered to. In this respect it seems curious that dogs coming from Ireland and the Isle of Man should be exempted; much greater safety would be attained if these two islands were not excepted. That six months is not a sufficient length of time for the continuous application of the muzzle or of quarantine has been demonstrated upon more than one occasion. The period of incubation of the virus in the system is at present known to be indefinite and the order ought to be enforced for at least twelve consecutive months. *One year's strict and universal muzzling might see us free from a terrible pestilence.*

Now that the public have had their outburst of feeling at the indignities put upon their pets, and that the latter have got used to their wire cages, it would be a matter of regret if Mr. LONG returned (and it is quite evident he does not intend so to do) to the half-hearted measures adopted by previous administrators when attempting to grapple with this disease. We sympathise with the troubles of dogs and dog-owners and in particular we dislike the partial working of the Order, but the good that it has done is unquestionably immense. Surely from a humane and common-sense point of view the saving of human lives, even if only comparatively speaking a few, is to be considered as being far more important than the inconvenience caused to the whole canine race, especially as a number of the latter are also saved from a horrible death. Prolonged isolation of a wide ring around infected districts, the compulsory notification and slaughter of all diseased or suspected animals, together with stringent measures regarding the importation of dogs from all parts outside Great Britain are the only means by which the Government can hope to attain complete success in an attempt to stamp out rabies and to keep the country free from the disease. The example of the treatment of cattle plague, and in recent times of pleuro pneumonia, cannot be too closely followed. These diseases are now practically stamped out and if proper measures are adopted there is reason to hope that rabies may be stamped out in the same manner.

ANÆSTHESIA of a sort has been practised from times immemorial, certainly from that convenient legal period "beyond the memory of living man." It was taught by HUMPHRY DAVY in 1799 and again by FARADAY in 1818. The properties of ether were well known to toxicologists and those learned in drugs and ether was inhaled long before MORTON gave his historic demonstration at Boston. HORACE WELLS'S claim to priority—and indeed his use of nitrous oxide gas in 1844 appears to have been the first public demonstration of an anæsthetic—cannot be overlooked. Even in the case of ether it appears that Dr. CRAWFORD LONG employed it as an anæsthetic in 1842. And if MORTON'S name is more prominently associated with ether as being the first to publicly demonstrate its effects SIMPSON'S advocacy of chloroform is at least as interesting. We refrain from entering into the miserable stories of JACKSON, MORTON, and the luckless WELLS; but with SIMPSON we find no self-seeking; all is enthusiasm and eagerness to get ahead with his "wonderful discovery." The long correspondence which he held with BIGELOW when that illustrious man sought to uphold his country's claim to the discovery of anæsthesia—a perfectly legitimate claim and one which SIMPSON had always conceded—never reveals lack of dignity or self-respect.

Dr. DUDLEY BUXTON in his oration to the Society of Anæsthetists, which we print in another column, had other matters to deal with besides chatty disquisitions on the history of his subject. The commanding presence of Dr. JOHN SNOW as a scientific explorer in the field of anæsthesia calls for more than passing comment. It is justly pointed out that no man, not even excepting SNOW'S pupil, friend, and biographer, the late Sir BENJAMIN WARD RICHARDSON, has done so much to make the study of anæsthetics a science as did SNOW. When his lectures on Narcotic Vapours were published men

Digitized by Google

began to realise that SIMPSON'S simple rules and equally simple physiological knowledge of chloroform left much to be desired. SNOW adopted the experimental method and soon elaborated his theory that the phenomena shown by animals under chloroform are the direct effects of different quantities of the narcotic contained in their blood. He analysed all the cases of death he could lay his hands upon and classed them according to his experimental results. The teaching of SYME appears to have been founded solely upon the practice of SIMPSON, nor does it appear at all certain that beyond a rough and ready plan of using large quantities of the anæsthetic and watching the state of the respiration SYME held any very definite views of his own. Certainly his practice was very successful and probably this fortunate circumstance has led his pupils to invest the surgeon with the credit of a method which undoubtedly belonged, as SYME himself averred, "to Dr. SIMPSON." The importance of the subject and the prominent place it has held in men's minds for the past half century are fully attested by the wealth of research and the mass of literature with which Dr. BUXTON had to deal in making his interesting oration as far as possible exhaustive. The general teaching of the oration may be summed up by saying that chloroform has been proved both by the light of physiological experiment and clinical research to be a highly dangerous body—a drug necessary for the equipment of the surgeon but one demanding the careful handling of responsible and skilled persons. While the earlier labours of BERNARD, BEST, SNOW, and SIBSON carry great weight, yet there can be no doubt that more recent methods have introduced far more exactitude into our knowledge of chloroform.

Whatever views, however, are entertained upon the action of drugs in the schools there is no doubt that the general public care far less about the science than the art. It is, according to Dr. BUXTON, even yet hopeless to expect that any method of giving chloroform will constitute the middle path of safety, "in spite of advertisements of instrument-makers and the assured utterances of doctrinaires"—to give his words. It is no doubt true, as was emphasised in the oration, that the large mass of evidence which has now been collected about the action of anæsthetics has been derived to a great extent from experiments upon the lower animals. And certainly "knowledge casteth out fear," so that we should expect the management of the chloroformed patient to be more exact and more safe now than it was formerly. If the death-rate does not appear to justify such a statement it is, in Dr. BUXTON'S opinion, because the practice of anæsthetics is in too many cases merely a matter of routine and the methods in vogue are too often faulty. If a fuller knowledge of the subject leads to a lessening of empiricism and a recognition of the importance of the scientific study of anæsthesia this celebration of the introduction of chloroform as an anæsthetic will not have caused time and energy to be spent in vain.

RIPON WORKHOUSE INFIRMARY.—The foundation stone of an infirmary in connexion with Ripon workhouse was laid by the Marquis of Ripon on Nov. 11th. The building will accommodate about forty patients.

Annotations.

"Ne quid nimis."

THE ANNUAL MEETING OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE result of the ballot of the Fellows taken in January of this year was so disappointing to those Members of the College of Surgeons who were desirous of direct representation on the Council that an explanation was naturally sought. It may be remembered that at a meeting of the Fellows in January, 1896, a resolution was carried by a very large majority of the Fellows present to the effect that it was desirable to give the Members direct representation on the Council. A not improbable explanation of the antagonistic result of the poll was offered—namely, that the "elucidatory statement" which accompanied the questions to the Fellows was misleading and was not impartially drawn up. This view was expressed in a resolution brought forward at the recent annual meeting of the Fellows and Members; it was introduced by Dr. Thomas Morton in a speech which was at once able and moderate in tone—a very agreeable contrast to the speeches of many Members, who unfortunately employ a vehemence which cannot but be regretted by the best friends of the Members' claims. Dr. Morton pointed out several items of the elucidatory statement in which the arguments advanced by the Members were not correctly represented. Mr. Henry Morris mentioned that on the committee of the Council which drew up the statement were two members of the Council who have always been consistent advocates of the claims of the Members. It was almost too much to expect that an elucidatory statement could be drawn up which should be satisfactory to both parties. At present the adverse vote of the Fellows, although there were more than 400 Fellows who did not vote, bars the way of any extension of the Franchise to Members, and we cannot help thinking that it will be long before any active progress in reform is made. The second resolution before the meeting referred to the claim put forward by the Council in March, 1896, that it represented the Members as well as the Fellows. It was obvious at the time that in the Council's resolution the word "represent" was used in two different meanings, and therefore the resolution could hardly be taken seriously, and the fact that it was carried in the Council by only 11 votes to 8 deprived it of much of the importance it might otherwise have had. The burning question of medical aid associations formed the subject of the third resolution. Of the harm done to general practitioners by these associations no one acquainted with the facts can have any doubt, and they increase in number and extent every day. The Royal College of Physicians of Ireland has uttered a distinct protest against any of its *alumni* associating themselves with such trading bodies, and pronouncements less forcible in tone have been put forth by some other colleges; but the Royal College of Surgeons of England has hitherto contented itself with expressing its willingness to consider any individual case if brought before its notice. The resolution carried at the meeting at the College of Surgeons last week asked the Council to declare that acting as the paid official of one of these associations is "disgraceful in a professional respect." This the Council decline to do, but they reiterate their willingness to investigate particular instances, and we should advise the Society of Members to collect evidence of canvassing for patients by an association employing a

Digitized by Google

Member of the College. The action of the Council in such a case will be awaited with great interest.

THE LACK OF ACCOMMODATION FOR LUNATICS IN LIVERPOOL WORKHOUSES.

ON more than one occasion attention has been drawn in the columns of THE LANCET to the deficiency of accommodation for pauper lunatics in the Lancashire county asylums as well as in the workhouses of the parish of Liverpool and the West Derby and Toxteth unions, and to the consequent refusal of the workhouses' authorities to receive from the hands of the police persons mentally deranged Last week Mr. T. E. Sampson, the coroner for Liverpool, acting in a magisterial capacity had occasion to allude to the subject from the bench and to deplore this unfortunate state of things. He said that frequently persons were found wandering at large apparently insane and unable to give a coherent account of themselves. The police in the exercise of their duty conveyed such persons to the bridewell, where they were examined by a medical man who, if satisfied of their mental aberration, gave a certificate recommending their admission to the workhouse. Up to a recent period no serious difficulty had arisen, but latterly the authorities of the Mill-road Infirmary of the West Derby Union had declined to receive such cases, stating that they were already full and had no further accommodation. The result was that the unfortunate individuals had to be taken back to the bridewell and dealt with by a magistrate who was thereby placed in a position of great difficulty and perplexity. It appeared to him that something ought to be done by the proper authorities to end this lamentable deadlock, fraught with much danger to the public as well as to the persons afflicted, and to avoid what he feared might develop into a public scandal. Mr. Sampson's prognostications had not long to wait for verification. A few days subsequently, on the 22nd inst., an inquest was held by him touching the death of Alfred Rigby, aged twenty-two years, who died through being run over by a railway train at Sandhills station on the 19th inst. The evidence showed that Rigby, who had been temperate and steady in his habits, had latterly become mentally deranged and that he was taken on the 13th inst. to the Mill-road Infirmary on the recommendation of a medical man to be temporarily detained there with a view to his subsequent removal to an asylum, but owing to lack of accommodation he could not be admitted. Rigby went to see his uncle on the following Friday, nothing further being heard of him until news was received of his having been killed at the station. The evidence of two witnesses pointed to suicide and a verdict to that effect was returned by the jury. The coroner, in his address to the jury, said that he did not blame the workhouse authorities, but that one could not help thinking that if there had been room in the workhouse this young man would probably have been cured of his trouble and his life saved. Mr. Cleaver (the clerk of the West Derby Union, who attended at the inquest on behalf of the guardians) said that the workhouse was considerably overcrowded, lunatics who had been certified for removal to asylums by order of magistrates being compulsorily detained (thereby straining the Act of Parliament) for want of accommodation in the county asylums. If the twenty acute cases had been removed to asylums there would have been a margin for accommodating sixteen cases, so that the deceased would not have been refused admission. He also stated that for the past six or seven years the guardians had been calling attention to the lack of accommodation in the county asylums. All these circumstances truly call for the interference of the Home Office and the Local Government Board to insure against a recurrence of such a lamentable instance as that recorded above.

THE STATE OF THE STREETS.

WE desire to call the attention of the London vestries, and more especially the vestry of St. Martin, the London County Council, and the Society for the Prevention of Cruelty to Animals, to the disgraceful state of the streets. We are not alluding now to the curse of newsboys, piano organists, and other disturbers of the public peace, but to the sufferings and struggles of horses trying in vain to drag heavy loads over pavements which are abominably greasy and afford no foothold whatever. We have only too frequent opportunities of observing this state of affairs from the windows of this office, and we have no hesitation in saying that the condition of Bedford-street is a disgrace to any civilised city and more than a disgrace to a city which prides herself upon being the first city of the world. Is it a question of money? Rates, as every ratepayer knows, are very high; but if a quarter of the money expended upon free libraries, other than reference libraries, which are chiefly used for those out of work to sit in and consult the advertising columns of the daily press for work and upon the School Board for erecting ridiculously expensive buildings upon the finest site in London and for giving "primary education" in thirty-six different subjects were diverted to making London a decent, clean, and well-swept, cleanly-paved city, money would be saved to horseowners and contractors, to say nothing of the omnibus companies and their shareholders, while the man in the street could drive or walk abroad without being daily harrowed by the sufferings of horses.

THE RECENT GREAT FIRE.

PROPERTY covering four and a half acres has been destroyed at a loss of, speaking roughly, £1,500,000. This is the bill for the last great fire, leaving out of consideration the thousands of hands thrown out of work. In view of the rebuilding which no doubt will be commenced as soon as the area affected is cold enough to make a beginning is it too much to hope that some attention will be paid to the first principles of construction? That fires in the City of London commit the fearful ravages they do is, we are quite certain, entirely due to our abominable modern method of building. The enormous warehouses are mere shells consisting of an iron framework lightly filled in with bricks, a little concrete, and large sheets of glass. When completed the structure is said to be "fire-proof." Of course, glass, iron, brick and concrete are all non-inflammable, but once a fire gains a hold of the very inflammable contents what happens? The iron girders and beams expand with absolutely irresistible force and the whole building collapses. Were the good old style of using solid oak beams to be made compulsory the ruin wrought by expansion would be avoided and the very progress of the fire much delayed. It is, we suppose, hopeless to try to insist that a certain amount of isolation for buildings shall be made obligatory, or at least that the height of a building shall bear some sensible relation to the width of the street that it is in; but we should have thought it would have been cheaper in the long run to leave a little more land vacant than is at present the fashion. Another point to which we wish to draw attention with reference to this particular fire is the fact that nearly all modern silks are grossly adulterated and consequently far more inflammable than pure silk, a fabric which burns with great difficulty. Sophistication is especially common in the case of black silks. Again, it is reported that there was a large gas

Digitized by Google

main in full blast in the centre of the fire without apparently there being any means of cutting off the supply. We do not see why the gas could not be turned off at various places along the street mains, as is the case with the water pipes. The efforts of the firemen must be seriously hampered by the huge jets of flaring gas, the flames of which are frequently to be seen enveloping inflammable structure which had long been put out only to be ignited afresh. The heat of a big conflagration such as that which recently took place in the neighbourhood of the General Post Office is sufficient to rapidly convert the jet of water from the hose into steam, and steam in contact with glowing charcoal produces inflammable gas—i.e., a mixture of hydrogen and carbon monoxide. Is this, perchance, any explanation of the difficulty of extinguishing the fire of buildings when in the official reports they are described as "well alight"? Water poured upon a glowing mass of embers may thus accentuate rather than stifle the blaze. We wonder that now carbonic acid gas can be obtained compressed in immense quantities in steel cylinders it is not tried, especially in the early stages of the fire, as an adjunct to water which after all is only applied to reduce the ignition temperature and not in any way as a non-supporter of combustion. With reference to the rumour that the supply of water was inadequate Colonel Rotton stated to the London County Council on the 23rd inst. that "there was plenty of water in every place."

PUBLIC HEALTH OF INDIA.

THE *Calcutta Review* for October last contains an article on "The Public Health of India" which calls for some attention on our part. The writer of the paper in question, while freely admitting that the "common sense" of England long ago recognised the immediate value of sanitary improvements in the shape of pure water, fresh air, and the removal of offensive matters from the neighbourhood of dwellings, adds that having opened its pockets to the demands of sanitarians in these respects, it was too much to expect it to give money for the provision and upkeep of laboratories and hygienic institutions the utility and profit of which were not so immediately apparent. It was soon found, however, that modern systems of scientific investigation and experiment led to results capable of being applied to practical hygiene and that these methods could not be neglected without prejudicially affecting the cause of public health and were, moreover, essentially necessary on the part of any country engaged in the contest for hygienic supremacy. As far as England is concerned she has learned this lesson and profited by it, but with India the case is different. All who know that country must acknowledge the great difficulties that have to be encountered there and more especially so at the present time. It has been said that the Indian Government takes a long time to make up its mind to do a thing, but having made it up it generally does it well. The matter is confessedly very important for India, and the need for undertaking and systematically prosecuting scientific inquiries into the causes of numerous diseases of that country is generally recognised. The Indian Government is most probably well aware of this and desirous of encouraging all attempts in this direction, but it nevertheless hesitates to make up its mind or to get any adequate grip of the requirements of the case. What is wanted, as we have said long ago, is the establishment of some really good institutes of public health in India superintended and conducted by a carefully selected staff of properly trained men, furnished with all the necessary appliances for the scientific investigation of disease and the study of hygiene. There should also, we think, be some local system analogous to that which obtains in this country organised at the different stations and cantonments of India for watching the public health and for investigating the facts connected with outbreaks of disease while these are fresh in the recollection of all concerned. The sanitary authority of a district or large cantonment might usefully be composed of a specially selected medical officer associated with an officer of the Public Works or Royal Engineer Services, and their reports might be furnished, together with their practical recommendations, to the principal medical officer of the district or station All questions requiring further scientific or bacteriological investigation might be referred by this or any other local authority to the Public Health Institute for that purpose. It is not merely a collection of statistics that is required, although these should of course be available. The temptation to calculate rather than analyse and to have recourse to a mechanical process in cases demanding a thorough and probably laborious examination is always present, but it is inapplicable and leads to no reliable conclusions. The medical services in India contain a number of young medical officers highly trained in modern methods of research, some of whom have public health diplomas, as well as some older and more experienced officers who have devoted themselves to this class of subjects, and the Indian Government cannot therefore have any difficulty in selecting the proper men for the purpose.

HYSTERIA IN EXCELSIS.

RARELY in the dismal annals of a coroner's court has a sillier or more pitiful story come to light than that related at Acton before Mr. Vere Benson on Nov. 22nd. The inquest was upon the body of a boy named Thomas Linklater, aged fifteen years, an assistant in the Assay Department of the Royal Mint, who committed suicide by taking cyanide of potassium on Nov. 10th. At the inquest William Hubert Antram, on the advice of his solicitor, elected to make a statement. Before doing so he was cautioned by the coroner in the usual way. This statement as reported in the *Times* ran as follows. He said he had known Linklater over twelve months. Early in the year he said something about taking his own life, but he afterwards said he had only been joking. On the Tuesday night before the occurrence he said something about taking poison and asked witness if he would do so. Witness, thinking he was joking, said he would. Linklater said, "You are not in earnest," and witness replied, "I am about as earnest as you are." On bidding him "good-night" Linklater said he was bringing some stuff the following night. The coroner then read the following letter which was found in Linklater's shorthand book: "This is to state I, Thomas Linklater, of Eastbury-grove, do mean to take this evening some prussic acid or cyanide of potassium in a bottle of ginger beer and thus end my miserable existence; and this is also to state that William Antrim, of Cranbrook-road, Chiswick, does mean to do the same. We shall go over into the meadows at about 10 o'clock and take the poison. Signed on Nov. 10, '97.—Thomas Linklater and William Antrim." Antram also told Dr. T. H. Bishop, of Chiswick, that Linklater had taken poison and had been sick. The jury returned a verdict that Linklater had committed suicide by taking cyanide of potassium, but exonerated Antram from aiding or abetting. However, they requested the coroner to censure him for the foolish part he had played. We do not know whether the unhappy Linklater was descended from a neurotic stock, as he probably was, or whether he is one more victim of the absurd system of over-pressure in education which is fostered by the Education Department and the various school boards. The old system of education had its faults but at least it inculcated habits of discipline and obedience. The modern system apparently

Digitized by Google

does neither if we may judge by the recent reports of free shooting by light-hearted youths in the streets, while the strain it places upon delicate and unwholesomely bred children is often intolerable. So our hospitals are filled with the choreic and broken-down puny child, who sometimes dies, but if restored to comparative health is apt to develop into the unbalanced, weakly-minded adolescent, exhibiting the lack of mental stability which led the unfortunate Linklater to "end his miserable existence."

THE WORKHOUSE INFIRMARY NURSING ASSOCIATION.

THE Executive Committee of the Workhouse Infirmary Nursing Association, 6, Adam-street, Strand, W.C, held a meeting on Oct. 13th, when the following resolutions were passed: 1. "That the Executive Committee, after long and careful consideration, is of opinion that the time has arrived when the work of the Association must of necessity cease for the following reason—the impossibility of adequately meeting by private effort alone the demand for trained nurses in Poor-law infirmaries, under the prevailing conditions, viz., (*a*) inadequate financial support to meet the expenses of training, (*b*) lack of suitable candidates for training; and (*c*) the anomalous position of trained nurses in country workhouses. The committee consider that steps should be taken to urge upon the Local Government Board that the whole question of nursing in Poor-law infirmaries should be undertaken by a State department or should be the subject of a departmental inquiry." 2. "That a meeting should be called in order that the views of the Executive Committee should be laid before the general committee and the subscribers." A meeting will accordingly be held at St. Martin's (small) Town-hall on Dec. 2nd at 3 P.M., when the chair will be taken by Mr. E. Boulnois, M.P. The Association has sustained a heavy loss by the recent death of its president, the much-lamented Duchess of Teck.

HOSPITAL BOARDS AND MEDICAL STAFFS.

THE regrettable incident at the Glasgow Western Infirmary, where the board of management has somewhat arbitrarily deprived an eminent surgeon of nearly one-fourth of the whole number of beds hitherto placed at his service, has opened up a question of some importance to our medical charities. Whatever may be the decision on the special point at issue arrived at by the general meeting of subscribers to that particular institution which is being held as we go to press, there will still remain the question so ably and fully raised by the *Glasgow Herald* of the 17th inst. This question is, What share ought to be taken by the medical staff in the management of a hospital? In the Western Infirmary, as in many other hospitals, the medical staff are practically excluded from the government, and it may not, therefore, be surprising, although it is much to be regretted, that acts are done affecting the privileges and interests of the medical officers in which they have no share. At the same time it is only fair to state that as a general rule the recommendations of medical staffs are loyally carried out by the lay committees. It is when the initiative in medical matters is taken by the latter that difficulties are apt to arise. It would appear that even in those hospitals where the staff does share in the management the amount of their participation varies within wide limits. In some hospitals every member of the staff is entitled *ex-officio* to a seat on the board of management; in others in order to secure this privilege he must first qualify as a governor; in others, again, two or more delegates or representatives of the staff have seats on the board; and in others there is a kind of dual control — matters affecting finance and general management being directed by a lay board, those concerning the medical affairs by a medical committee, the decisions of which are, however, subject to the approval of the board of management. Now the question as to which plan is most desirable in the interests of the hospital may be fair subject of debate, but surely no one can contend that the medical staff should have no voice at all in the institution to which they give their services, upon which, indeed, its reputation mainly is founded. In the interesting reports published by our contemporary some strong testimony is given in favour of the direct participation of the medical staff in management by those who have had opportunities of contrasting a present system which gives them this share with a past system in which they had no seats on the Board. Their testimony is unanimous in approval of the new régime, which, wherever it has been tried, has been attended with the happiest results. Such a system of joint management appears on the face of it as preferable to the separation of the two elements into two distinct committees, for this latter plan must occasionally lead to misunderstandings that would never arise were the medical staff joined with the lay governors in one board. Theoretically, we believe that the justest course is to admit all the members of the acting honorary staff to seats on the board; but in practice such a plan must in many instances give too preponderating a voice to the medical members. Therefore, on the whole, we think that a certain number of seats on the board of management might well be assigned to members of the staff acting as delegates of the whole body. Were such representation the rule questions such as that which has led to so grievous a conflict in Glasgow and many others of less vital import which from time to time disturb the harmonious working of a hospital might be wholly avoided. There can be no desire on the part of the medical men to interfere in the general and financial management of the institution, but they are deeply interested in all that pertains to the care of the patients and they ought to be in a position to express their views and wishes on all such subjects with the certainty that they will, if feasible, be carried out.

OZONE.

WHETHER ozone plays an important part in the hygiene of nature is a moot point. Pure ozone is unquestionably poisonous. In air which is largely polluted with organic matter, as is the air of London and other large towns, small quantities of ozone cannot obviously live long. It is of course a powerful oxidiser and the oxygen with which it is surcharged is soon absorbed. It is found, however, in distinct quantity in the pure air of the country and, as everybody knows, in sea air. Its occurrence in air is invariably connected with the existence of water generally in motion. Thus the wind blowing over the sea waves or over the waves of a lake or the air in the immediate neighbourhood of a waterfall or spray contains a notable amount of ozone. Of course ozone must to some extent exert a purifying influence upon the air, but this can only be of importance when the ozone occurs in distinct quantity or when it is being constantly evolved, as over the surface of the sea. Doubtless sea air and mountain air owe their beneficial qualities to their purity which in some measure is due to the action of ozone. This fact has led to the devising of apparatus for the simple and easy production of ozone in hospitals and large buildings. It may not be generally known that a very simple and effectual way of bringing ozone into the house consists in first suspending moist linen sheets in a keen dry wind, and afterwards hanging them up in the house. The air in the room will thus become considerably charged with ozone and its presence will be easily detected by its peculiar smell, while a moistened starch iodide paper will instantly turn blue. Why ozone is accumulated in wet clothes in this way

Digitized by Google

is not quite understood, but it may be due to the rapid passage of the oxygen in air over a large wet surface. It is not improbable that this interesting phenomenon plays an important part in the real hygienic cleansing of our linen articles of clothing. In big laundries when the not quite dry linen is brought in after having been exposed to a cold, dry air for a short time the smell of ozone is almost more than is agreeable.

"SCOTCH HAMS."

IN THE LANCET of Oct. 2nd, 1897, we commented upon the case of some tradesmen who were convicted of selling American hams as Scotch hams and "finest Irish hams" at Richmond, Surrey. A very similar set of cases were heard on Nov. 16th at the South Western Police Court before Mr. Marsham. In the first case Messrs. Frost and Co., of Lavender-hill, were, together with Horace Nice, the shopman, charged with selling an American ham as Scotch. The purchaser asked for a "nice Scotch ham," and Nice supplied him with one which he, Nice, said he had been told to sell as Scotch. As a matter of fact, said the witness, it was an American ham. Mr. Ricketts, in defence, said that there had been no imposition. There was no such thing as a Scotch ham, although this particular ham came from a Scotch firm of curers. Mr. Marsham acquitted the defendants of acting wilfully, but he fined Messrs. Frost £5 and £3 3*s.* costs, and Nice £1 and 2*s.* costs. In the next case Messrs. A. J. Palmer and Co., of High-street, Clapham, and Charles Bowden, their assistant, were charged. Mr. Moore, an inspector of the Bacon Curers' Association, who gave evidence as in the last case, said that Bowden asked him, "What kind of ham—English, Irish, or Scotch?" Moreover, the defendants had a regular price list, in which Scotch hams were priced at 8½*d.* a pound. Messrs. Palmer and Co. were fined £10 and £3 3*s.* costs, and Bowden was mulcted in £1 and 2*s.* costs. As we said in our former article on the subject, the sooner the suggestion of the Select Committee on Food Products Adulteration that offenders should be required to publish at their own expense a notice of their conviction passes into law the better.

HOMES FOR DESTITUTE CHILDREN.

ONE of the most important social questions of our day is what to do with our destitute children. It is important not merely from the point of view of humanity, but the very welfare of the State is bound up in this problem and put shortly the matter divides itself into two heads. Shall we rear a race of lawless, ignorant Ishmaels or shall we bring up children to be disciplined, God-fearing, law-abiding subjects. There are, of course, blackguards in every class of society, but beyond home influence there stands for the upper and upper middle classes the wholesome influence of the public school, and no one will deny that for teaching a boy to know his place, for knocking all nonsense out of him, and for generally fitting him for his work in the world there is nothing like an English public school. Among the lower and lower middle classes no such provision exists. We will not here refer to Board Schools but will confine our remarks to industrial schools, although some of these, in London at any rate, come under the control of the School Board. But the barrack industrial school is a dead failure. Here is discipline, indeed, and too much of it. The children are drilled and guided until they become merely wheels in a machine, and just as one cog-wheel is of no use by itself so the barrack-bred child when turned out into the world is useless. For this in London we pay about 11*s.* 6*d.* per child per week. In some towns however, notably Bradford and Sheffield—we quote from the *Bradford Observer*—the authorities are trying the cottage home system with, at present at any rate, admirable results. First as to the expense; the Bradford figures are not available yet, but the cost at Sheffield comes out at 7*s.* 9*d.* per child per week. The Bradford plan is to have eight children in a home and every home is under the care of a "mother" who is responsible for the care and cleanliness of the children. In these homes the children take part in the house-work, cleaning, cooking, washing, and bread baking, so that they get some idea of how daily wants are supplied and, although they may not be able to speak French or play the piano like the applicants for a shop boy's place mentioned recently in the daily press, they will probably be more useful and more sure of getting work in after life. Of course we do not pretend to consider this system to be as good as a real home, but for the unhappy children who have no home—and there are only too many of them—it seems to us the best hitherto devised. Bradford may well be proud thereof; meanwhile we can only hope that before long the cottage home system will be universal.

THE MOUNTING OF COVER-GLASS PREPARATIONS.

IN the current number of the *Deutsche Medicinische Wochenschrift* Dr. Peter Kaatzer, of Hanover, describes four instruments which he has found particularly useful in the manipulation of cover-glass preparations of objects for the microscope. The principal one is the upright forceps (Stehpincette), some idea of the shape of which as shown in the engraving may be given by supposing the bent part of a pair of sugar-tongs to be flattened and spread out, so that if required they will stand on this part with the points directed upwards. The inner surfaces of the tips of these forceps are roughened and have also one longitudinal groove in each, enabling them to hold a cover-glass either by opposite surfaces or by opposite edges. The spring of the forceps tends to close the points, so that the cover-glasses are held securely and without risk of being broken, and they are released by pressing two knobs which move the tips apart. When the cover-glass is held by the edges, the forceps being in the upright position, it is level and at a convenient distance from the work-table, so that the object may be arranged with needles or spread out as may be desired, or stained, or dried, or heated by holding a lamp under it. For the preliminary examination of objects under low powers he uses trays of black vulcanite three and a half inches in diameter. His needles are not of the usual pattern, but are made of platinum and are scalpel-shaped. For quickly drying an object on a cover-glass at the ordinary temperature he prefers the current of air produced by an indiarubber hand-bellows.

THE DANGERS OF GAS COOKING-STOVES.

IT might be thought that when persons are dealing with coal-gas every precaution would be taken to avoid the risks of accidental ignition of the gas, with probable explosion. That this is not so, however, is clear from the accounts which appear almost day by day in the papers of coal-gas explosions happening through a leak in the pipes, which leak has been sought and found by the aid of a naked flame. There does not, however, appear to have been negligence in a case reported recently where a serious explosion resulted on opening the door of a gas cooking-stove. The cooking-stove in question was supplied through a "penny-in-the-slot" meter which, owing to its refusal to yield gas on putting pennies in the slot had recently been changed for a new one. The new arrangement was tested and found satisfactory so far as regards the ring burners on the top of the stove. One of the rings was afterwards used to boil the water in a kettle, and later a chop was about to be placed in the oven. On opening the door,

Digitized by Google

however, in accordance with the directions enjoined by the gas company an explosion occurred, causing serious injuries to the cook. This was the subject of an action, and eventually judgment was given for the plaintiff for £50 with costs. It is clear that the plaintiff had acted upon the gas company's directions and had not turned on the supply to the oven burners before opening the oven door. What had most probably happened was a leak from the burners in the oven, the escaping gas filling the oven chamber forming an explosive mixture which on opening the door by some means or other came into contact with the flames of the ring burner on the top. This occurrence shows the necessity of taking the simple precaution of ventilating the oven so that there may be no possibility of the contained air, mixed perhaps with gas, coming into contact with outside flames. A stove, however, that requires such a precaution is obviously defective in construction, and in view of the great number of gas-stoves now in use for cooking purposes the gas companies letting them out for hire should, we think, have the stoves inspected from time to time both in the interests of their customers and themselves. Moreover, we have recently learned on good authority that the great fire last week had its origin in a gas cooking-stove which was defectively connected with the service pipe.

THE TRAINING OF MISSIONARIES.

IN THE LANCET of Oct. 10th, 1896 (p. 1023), we commented on the remarks made by Dr. Harford-Battersby at the Church Congress last year. This speaker pointed out the necessity for missionaries using every precaution to keep their health, although they might expect Divine protection. The same gentleman has recently returned from the Niger and he is again very emphatic on the point that it is most important that missionary societies should give more attention to the health of their workers while in the foreign field. It seems a matter deserving of grave censure that men and women should be sent, as is sometimes the case, to a deadly climate, like that of West Africa for example, without the slightest medical training and with very little knowledge of how to take care of their health amid unwholesome surroundings. That they should be told to live in "faith" that they will be protected by "Divine Providence" from endemic diseases whilst living in those climates is almost as bad and useless as asking anyone to jump off the Clifton suspension bridge in "faith" that they will escape harm; people have been known to survive the fall, but the chances are greatly against it. Or perhaps a closer analogy is the second temptation and its answer, described in the Gospel according to St. Matthew, iv., 5–7. Some medical knowledge is essential to European missionaries who are sent to reside in unhealthy climates, not only that their lives may be spared but that they may carry out the work for which they are intended. The knowledge will help them in many ways. He whom they serve knew well the influence on the common mind of the healing art and used it frequently as a demonstration of His power. The means which He has given us for the relief of sickness makes the greatest impression on the savage mind and thus forms an additional argument that the missionaries should have some knowledge of medicine and the means of employing that knowledge. To send out missionaries, however, without any medical training or without the presence of a medical man in the neighbourhood is approaching very nearly to the doings of "the Peculiar People" so justly condemned by one of our judges in the Central Criminal Court. We are not preaching "coddling" the missionaries, but would strongly urge that the knowledge which we have suggested places a great weapon in their hands.

SUBSTITUTION.

WHEN will shopkeepers understand that it is a fraud to supply a customer with a substitute after he has asked for the real thing, be it food, drug, or article of clothing? They even go further and have the impertinence to suggest at times that the substitute which they tender is altogether a superior article to the original that is asked for and better suited to the health of the purchaser! A grotesque instance of this kind recently occurred when the Swansea Grocers Association, at a meeting held on Nov. 16th, discussed some recent prosecutions which had taken place because of the substitution of tapioca for sago. Strong protests were raised against the prosecution, it being stated that it was a general practice and that the customer procured a superior article. It is to be hoped that the law will continue to administer a strong rebuke to this erroneous notion. Tapioca is not sago or sago tapioca, and there are important dietetic differences between the two. The case just quoted is only another example of a very common kind of fraud—namely, that of palming off upon the public a substitute the attribute of which is in general its cheaper price. As we have pointed out before, it seems to us that the Sale of Food and Drugs Act might be conveniently shortened into an Act simply to provide against substituted articles being tendered for the real and for the supply of articles of standard quality. If the application of such an Act could be effectually worked we should hear less of those cases of fraud in which cotton-seed oil is substituted for olive oil, ox fat for butter, beet sugar for cane sugar, "flannelette" for flannel, "linenette" for linen, and so on. In fact, we should like to see an Act in operation similar to the Merchandise Marks Act, which shall provide that all substitutes must be very legibly labelled with the word "Substitute" in addition to whatever fancy title may be applied. We have not one word to say against substitutes, which doubtless supply a distinct want of the people, but when substitutes are palmed off for the real articles the crime is none the less because they happen to be good of their kind and harmless.

A SMOKING concert was given, under the auspices of the Cambridge Graduates Medical Club, in the Banqueting Hall, St. James's Hall, on Nov. 17th. The members of the Oxford Graduates Medical Club were invited and were well represented among the guests. The attendance was good, 213 tickets being handed in during the evening. Excellent music was provided by Dr. A. Shadwell, Dr. S. H. Habershon, Dr. Blumfeld, Dr. Ll. Powell, Dr. C. N. Chadborn, Dr. W. J. Harris, Mr. Cole, Mr. L. R. Marshall, Mr. Pollard, and Mr. Nixon. The proceedings, which were informal and thoroughly social, terminated shortly before midnight.

A MEETING of the Council of the Metropolitan Hospital Sunday Fund will be held at the Mansion House to-day (Friday) at 3 P.M., when amongst other business the convening of the next annual general meeting of constituents will be ordered and the question of the date of Hospital Sunday for 1898 to be recommended to the constituents will be considered.

H.R.H. THE DUKE OF CONNAUGHT will take the chair at the festival dinner in aid of St. Mark's Hospital to be held at the Whitehall Rooms, on St. Mark's Day, Monday, April 25th, 1898.

THE Council of King's College, London, have received an anonymous donation of £15,000 towards the liquidation of the College debt.

The Lancet Special Commission

ON THE

METROPOLITAN WATER-SUPPLY.

XX.[1]

NEW RIVER COMPANY—*Continued.*

THE WELLS, PUMPING-STATIONS, AND RESERVOIRS.

A GENERAL survey of the present course of the New River having been given we proceed to describe the stations of the Company.

Broad Mead well (see C on general Map[2]).—At Broad Mead a boring was made in the hope that the greensand might be reached and that it would afford a supply of water. The bore of the well was taken down a distance of 831 ft., the size of the bore being 20 in. at the upper part and 16 in. at the lower part. The greensand formation was not found. A well 30 ft. in depth was sunk, but no large supply of water can be obtained here. The amount has been estimated at 500,000 gallons a day, but the pumping arrangements are, we believe, not capable of raising this quantity.

Pumping arrangements.—There is a simple horizontal engine with a centrifugal pump and a boiler of the locomotive type. The engine is of 16 horse-power. When visited on Jan. 5th and June 16th this engine was not working; it is rarely used. The water is pumped from the well into the river, which at this point contains the water derived from the Lee and from Chadwell spring.

Amwell End well and pumping station (see D on Map).—The well is 72 ft. in depth. Chalk occurs at the depth of about 36 ft. below the surface; the part above the chalk is lined with iron.

Pumping arrangements.—There are two reciprocating pumps which have barrels 22 in. in diameter. These are worked by a simple condensing vertical engine of 50 horse-power. The steam is generated by two Galloway boilers. The amount of water which can be obtained here is estimated at 1,500,000 gallons daily. The water is pumped into the river through iron pipes. It was stated on June 16th that the pumps had been at work for twelve hours daily from the month of April.

Amwell Hill well and pumping station (see E on Map).—This station is situated on the upper bank of the New River on the steeply sloping side of Amwell Hill, at a level of about 20 ft. above the New River. The well is 90 ft. in depth and goes into the chalk; it has headings and a bore hole. The shaft is lined with brick. From this shaft there are headings 6 ft. in height and 4 ft. 6 in. wide. From the centre of the shaft there is a bore hole 2 ft. in diameter at the upper part and 9 in. at the lower part. The bottom of the bore hole is 161 ft. from the surface. The amount of water which can be obtained daily is stated to be 3,500,000 gallons, and it is said that this quantity can be obtained day after day for a period of six months.[3] When visited on Jan. 5th the pumping arrangements were being overhauled and repaired. There is a beam engine of 50 horse-power and an inverted cylinder engine of 25 horse-power. The steam is generated by one Lancashire and one Cornish boiler. The water passes through a large brick culvert into the New River. At this station there is another small engine which is used for pumping water into the village; the water used for this supply is pure water from the well. No water from the New River is used for the local supply. With the exception of this small local supply no water was raised from the well from Nov. 21st, 1896, until the time it was visited on Jan. 5th, 1897.

Amwell Marsh well and pumping-station (see F on Map).—This station is situated on the lower bank of the river; it was completed in 1884.

Well.—There is a well 110 ft. in depth. The quantity of water which it is said can be obtained daily from the well is 2,750,000 gallons.

Pumping arrangements.—There are two simple vertical engines of 35 horse-power each. These work pumps through bell cranks. The steam is generated by two Cornish boilers. The water is all pumped into the New River. When visited in June the daily amount pumped was about 1,500,000 gallons daily.

Rye Common well and pumping-station (see G on Map).—This station is situated at the lower bank of the New River.

Well.—There is a well 200 ft. in depth lined with brick and iron cylinders to the depth of the chalk. The level of the water in this well on June 16th was 55 ft. below the surface. At this date the engines were worked for twelve hours daily and were raising about 2,500,000 gallons of water.

Pumping arrangements.—There are two vertical engines with inverted cylinders of 100 horse-power each. These work the pumps through bell cranks. Steam is generated by two Cornish boilers. The water is all pumped into the New River. It is stated that the well is able to supply from 4,000,000 to 5,000,000 gallons daily.

Hoddesdon well and pumping station (see H on Map).—The station is situated on the lower bank of the river. The well is 55 ft. in depth. Chalk was reached at a depth of 32 ft. from the surface. The amount of water which can be obtained is said to be 2,000 000 gallons daily.

Pumping arrangements.—There is a 50 horse-power vertical single cylinder engine which works two pumps through gear. The steam for working the engine is generated by a Lancashire boiler and the pressure used is 25 lb. All the water is pumped into the New River.

Broxbourne well and pumping station (see I on Map).—The well is about 200 ft. in depth. The diameter at the upper part is 16 ft. This well has two headings, one 300 ft. and the other 400 ft. in length. The amount of water which it is said can be obtained daily is 4,500,000 gallons. On July 16th it was 137 ft. below the surface. The level has been reduced to 145 ft.

Pumping arrangements.—There are three engines of 180 horse-power altogether. Of these two are vertical engines with inverted cylinders and the other a horizontal engine. The steam is generated by Lancashire boilers, and the pressure used is 65 lb. The pumps are worked through bell cranks. There are six pumps of which the cylinders are 14 in. in diameter and the stroke is 3 ft. The rate at which they are worked is 25 per minute.

Turnford well and pumping station (see J on Map).—The station is situated on the lower bank of the river. The well is 170 ft. in depth and has two headings of 220 ft. and 190 ft. in length respectively, and a bore hole to 1000 ft. in depth. The well is said to be capable of supplying 3,000,000 gallons daily.

Pumping arrangements.—There are two engines. One single cylinder side lever engine works bell cranks through gear, and an inverted cylinder engine works bell cranks directly. The steam is generated by two Lancashire boilers, and the pressure at which the engines are worked is 56 lb. Of the pumps two have cylinders 18 in. in diameter, a stroke of 2 ft. 6 in., and work at a rate of 27; the other two pumps have a diameter of 22 in., a stroke of 6 ft. 0 in., and work at a rate of 8 strokes a minute. The water is all pumped into the New River.

Hoe-lane well and pumping station (see M on Map).—The well is about 200 ft. in depth. Chalk occurs at a depth of about 100 ft. The amount of water which it is estimated the well could supply daily is 2,000,000 gallons.

Pumping arrangements.—The water is pumped by two horizontal engines which together possess 170 horse-power. The steam is supplied by three Lancashire boilers. The engines work the pumps through gear.

Bush Hill reservoir (see N on Map).—The reservoirs are situated in Bush Hill Park. A well was sunk here and a water tower built when the estate was laid out for building purposes. The well and reservoirs were taken over by the New River Company. The well is not now used. The water for the supply of the reservoirs is pumped from Highfield and is distributed to the surrounding district.

Southgate reservoir (see O on Map).—This reservoir is situated on the highest point at Southgate-hill, near Cockfosters-road and Chase Side-road. The area occupied by the

---

[1] Nos. I., II., III., IV., V., VI., VII., VIII., IX., X., XI., XII., XIII., XIV., XV., XVI., XVII., XVIII., and XIX. were published in THE LANCET of Feb. 20th and 27th, March 6th, 13th, 20th, and 27th, April 3rd, 17th, and 24th, May 1st, 8th, 15th, 22nd, and 29th, June 19th and 26th, Oct. 23rd, and Nov. 6th and 13th respectively.

[2] The map referred to in this article appeared in THE LANCET of Oct. 23rd, p. 1069.

[3] Mr. Mylne, the engineer to the Company, stated in 1852, in his evidence on the Metropolitan Water Supply, that the well then yielded 2,466,000 gallons daily.

Digitized by Google

station is about three acres, and it is surrounded by a 6-ft. brick wall; the reservoir occupies about one-third of the space. It is built of brick set in cement and covered by brick arches; the top is turfed over. Ventilation is effected through twenty iron gratings, 18 in. by 6 in. in size, which are placed at the sides of the reservoir. There is a circular manhole 4 ft. in diameter covered by York stone. The capacity of the reservoir is 1,000,000 gallons and the top water level is 308 ft. above ordnance datum. The water pumped here comes from the well at Betstile and from Highfield; it is all pure well water. The districts supplied are Southgate and Winchmore Hill. There is no electric communication between this place and the pumping station. A man is sent to the reservoir twice a day to note the height of the water.

Highfield (Edmonton) well and pumping station (see P on Map).

Well.—The well is about 200 ft. in depth. The diameter at the upper part is 15 ft. and at the bottom 11 ft. The upper 40 ft. of the shaft is lined with brick, and below that with iron cylinders to the chalk, which occurs at a depth of 116 ft. There are two headings, each about 30 ft. in length. The amount of water which the well is said to be capable of supplying is 3,000,000 gallons. When visited on July 20th the level of the water in the well was 160 ft. below the surface. The pumping had been going on continuously for a month. The rest level—that is, the height to which the water rises when pumping operations are discontinued for some time—is 60 ft. below the surface.

Pumping arrangements.—There is a pair of single cylinder vertical engines. The cylinders are 32 in. in diameter, the length of the stroke is 3 ft., and the rate at which the engines are working is about 28 strokes per minute. The engines work four bucket and plunger pumps through bell cranks. The diameter of the pump barrel is 14½ in.; the length of the stroke is 3 ft. The steam for working the engines is generated by three Lancashire boilers, and they are worked at a pressure of 50 lb. There is also a compound vertical engine which had a cylinder 15 in. in diameter and a stroke of 12½ in. This engine is used for pumping water to Southgate. The head of water worked against in pumping to Southgate is 250 ft. There is at this station the recording index of an electric gauge, which shows the height of the water in the Bourne Hill reservoir.

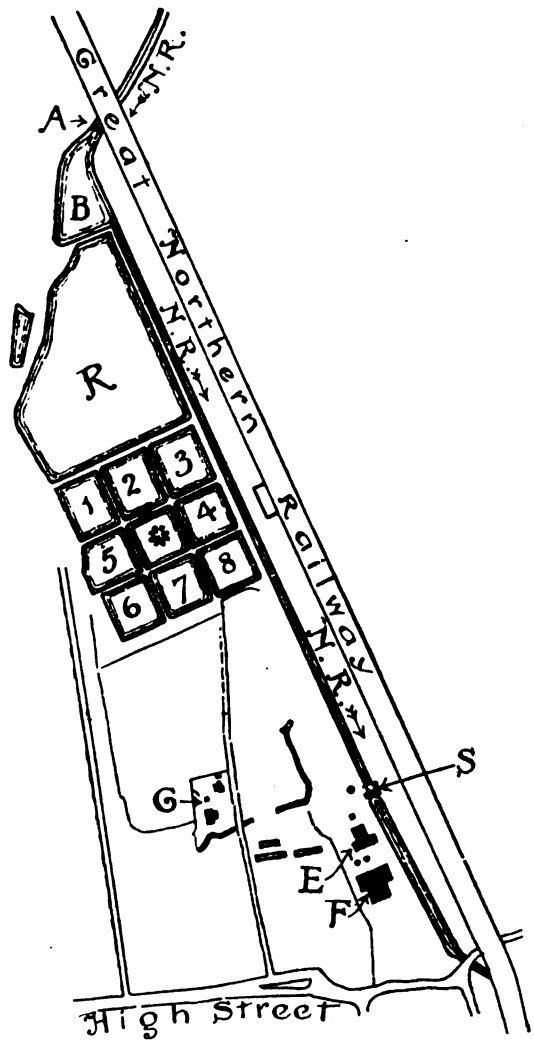
Bourne Hill reservoir (see Q on Map).—This is situated on the south side of Dog and Duck-lane, Southgate. It is surrounded by a wall on three sides and by a high oak fence on the side next to the road. The reservoir is built of brick set in cement, and is covered by brick arches on the top of which there is a layer of about 2 ft. of earth which is turfed over. There are twenty-four cast iron ventilators. The reservoir has a capacity of 1,500,000 gallons. The top water level is 195 5 ft. above ordnance datum. There is a floating gauge here which is in electric communication with Highfield engine house from which it is about a quarter of a mile distant. The communicating wire passes along the public high road. Water is pumped here from Highfield and the reservoir can also be supplied from the one at Crouch Hill, which is about two and a half miles distant. The water from this reservoir supplies Edmonton and part of Southgate.

Betstile well and pumping station (see R on Map).

Well.—At this station there is a well 142 ft. in depth sunk into the chalk.

Pumping arrangements.—The water is pumped by two horizontal engines of 12 horse-power each. These work pumps through gear. The steam is generated by two Cornish boilers.

The amount of water which can be obtained is estimated to be 500,000 gallons daily. It is used for the supply of the district around.



This place was formerly the property of the North Middlesex Waterworks Company.

Hornsey reservoir, filter beds, and pumping station (see S on Map, and Plan Fig. 1).—This station is situated on the lower bank of the New River at the foot of Muswell Hill and just to the west of the Great Northern Railway line. The water from the New River after passing the Hornsey grate-bridge (see Fig. 1, A), which has already been described, passes into the Hornsey basin (Fig. 1, B), a reservoir which has an area of about an acre. From the basin the water is conducted into the reservoir through a 48-in. pipe, guarded by a screw-cock.

Reservoir (Fig. 1, R).—There is an open reservoir, which occupies an area of eight acres and is capable of holding 8,500,000 gallons of water. The sides of the reservoir are lined with Kentish rag.

Filter beds.—There are eight filter beds, numbered 1 to 8 respectively. Of these, No. 1 when visited in July, 1897, was being re-made. Of the others, Nos. 4, 5, 6, 7, and 8 have vertical walls. Nos. 2 and 3 have sloping walls; these

FIG. 1.

Hornsey and Campsbourne Stations. N R, New River. A, Hornsey grate. B, Hornsey basin. R, Reservoir. 1, 2, 3, 4, 5, 6, 7, 8, Filter beds. * Storing place for sand. E, Hornsey sluice engine house. F, Hornsey engine house. G, Campsbourne well and pumping station. S, Hornsey sluice house.

will be re-made after No. 1 has been done. The central space between the filter beds is used for storing sand.

The upper parts and sides of the beds are lined with blue Staffordshire bricks. The old beds are formed as follows: sand, 2 ft.; fine shingle, 2 ft.; and coarse shingle, 1 ft. The floor of the filter bed is formed of perforated bricks set on edge, and the filtered water is collected in a central channel which is 2 ft. 6 in. square. Each filter bed has four 3-in. cast-iron ventilating shafts, which are situated at the sides of the bed, and none of the beds have central ventilating shafts. The sand is cleansed by washing with a jet of water working at a pressure of 100 ft. head.

Engine houses.—There are two engine houses close together called the Hornsey Sluice and the Hornsey. Water is pumped from the filter beds to Crouch Hill reservoir and to Hornsey-lane reservoir.

Hornsey Sluice engine house (Fig. 1, E).—Here is a pair of Worthington triple expansion pumping engines. These pump about 2,500,000 gallons of water daily to Hornsey-lane against a head of water 250 ft. They are capable of pumping

Digitized by Google

a much greater quantity. The steam is generated by three Lancashire boilers which work at a pressure of 125 lb.

Hornsey engine house (Fig. 1, F).—There are four beam engines of 110 horse-power each. These are worked by steam supplied by ten Lancashire boilers.

The water, which is derived partly from wells and partly from the filter beds, is pumped to Crouch Hill reservoir and to Hornsey-lane.

Between the Hornsey Sluice engine house and the Hornsey engine house there is an excellent bath-room, provided with hot and cold water, which is at the service of the workmen. The sanitary arrangements here are admirable.

At Hornsey there is a tramway over the river from the Great Northern Railway. This is used for the conveyance of coals to the engine houses.

Campsbourne well and pumping station.—This station adjoins the one at Hornsey. (See Fig. 1.)

Well.—The well is 215 ft. in depth. At the upper part the shaft is 15 ft. in diameter, at the lower part 10 ft. The well is lined with brick for the upper 100 ft., then with iron cylinders. Chalk occurs at a depth of 168 ft. This well does not contain any bore hole. The level of the water when visited on July 21st was 190 ft. below the surface. The rest level is about 100 ft. below the surface. The amount of water which it is stated can be pumped daily is 3,000,000 gallons. At the present time the amount pumped is on an average 1,500,000 gallons. Water is pumped to (1) the New River, and (2) Hornsey, against a head of about 10 ft.

Pumping arrangements.—There are two compound vertical surface condensing engines, the size of the high pressure cylinder is 18 in., of the low pressure cylinder 3 ft. The length of the stroke 2 ft. 6 in. The steam is generated by three Lancashire boilers working at a pressure of 80 lb. The engines work pumps of which the barrels are 17 in. in diameter, and the length of the stroke is 2 ft. 6 in. The rate at which they are worked is 30 strokes per minute.

Workshops.—At this station there is a large carpenters' shop and a well-fitted blacksmiths' shop. Here much carpentering work is done. The wood and iron work required on the river is now carried out by the Company's own servants and under the supervision of their own engineers.

Crouch Hill reservoirs (see U on Map).—The station is situated next Mount View-road and Ferme Park-road, Hornsey, 195 ft. above ordnance datum. The area occupied here is about 8 acres. There are two reservoirs covered with brick arches and turfed over. The slope of the sides is 1 in 6, and the reservoirs are built of brick set in cement. There is a cast iron ventilator. Each reservoir has an entrance pit covered by an iron roof. There is an electric gauge here which records the height of the water in these reservoirs. The recording index is situated at the Green Lanes station, whence the water is pumped. These reservoirs are capable of holding 12,000,000 gallons. They are used for the supply of Islington, of Hornsey, and of part of the city. The turf over the reservoirs is used by the Northern Heights Lawn Tennis Club. A caretaker's cottage is situated here.

(To be continued.)

THE ROYAL COMMISSION ON THE METROPOLITAN WATER-SUPPLY.

THE first meeting of the Royal Commission on the Metropolitan Water-supply took place in the Moses Room of the House of Lords on Monday last, Nov. 22nd. The Commissioners appointed, it may be remembered, were the Right Hon. Viscount Llandaff (chairman), the Right Hon. John William Mellor, Q.C., M.P., Sir John Edward Dorington, Bart., M.P., Sir George Barclay Bruce, C.E., Mr. Alfred de Bock Porter, C.B., Major-General Alexander de Courcy Scott, R.E., Mr. Henry William Cripps, Q.C., and Mr. Robert Lewis. With the exception of the Right Hon. J. W. Mellor all the Commissioners were present.

The London water companies and the county councils of London, Middlesex, and Hertfordshire were represented by counsel. Mr. Balfour-Browne, Q.C., and Mr. Freeman, Q.C., appeared for the London County Council; Sir Richard Nicholson for the Middlesex County Council; and Lord Robert Cecil for the Hertfordshire County Council. As counsel for the water companies Mr. Pope, Q.C., and Mr. Claude Baggallay, Q.C., appeared for the New River and Southwark and Vauxhall Companies; Mr. Littler, Q.C., and Mr. Lewis Coward for the Kent Company; Mr. Pember, Q.C., for the East London, Lambeth, Grand Junction, and West Middlesex Companies; and Mr. Richards for the Chelsea Company.

Before any evidence was taken the Commissioners had a preliminary private meeting and the inquiry did not commence until about forty minutes after the announced time which was midday. It may be well here to recall the exact scope of the inquiry, which will be best done by giving the terms of the reference, which are as follows:—

"To inquire: 1. Whether, having regard to financial considerations and to present and prospective requirements as regards water-supply in the districts within the limits of supply of the metropolitan water companies, it is desirable in the interests of the ratepayers and water consumers in those districts that the undertakings of the water companies should be acquired and managed either (*a*) by one authority, or (*b*) by several authorities; and, if so, what should be such authority or authorities. To what extent physical severance of the works and other property and sources of supply of the several companies and the division thereof between different local authorities within the limits of supply are practicable and desirable, and what are the legal powers necessary to give effect to any such arrangements.

"2. If the undertakings are not so acquired, whether additional powers of control should be exercised by local or other authorities; and, if so, what those powers should be.

"3. Whether it is practicable to connect any two or more of the different systems of supply now administered by the eight metropolitan companies; and, if so, by whom, and in what proportion, should the cost of connecting them be borne, and what are the legal powers necessary to give effect to any such arrangement."

At the opening of the proceedings Lord Llandaff stated that he would at once examine Mr. Cripps, the Parliamentary agent of the London County Council. The examination was founded on a long report which had been sent by the London County Council to the Royal Commission. This report was marked "Private" and was not in the hands of any one except the representatives of the County Council and the members of the Royal Commission. At a later stage of the meeting, however, Mr. Cripps put in two tables, summary analyses of the published accounts of the London water companies for the years 1895 and 1896, and these tables were given to the representatives of the water companies.

During the course of the examination Mr. Cripps said that he had been engaged in all the Parliamentary proceedings of the London County Council in reference to water companies and that he was acquainted with the views of the Council on the London water-supply, and that he appeared on their behalf to give any information he could on the subject. The London County Council had expressed their views on the question of the water-supply in a number of formal resolutions, and their latest opinion was: Firstly, that the undertakings of the water companies should be at once bought at their fair value; secondly, that the management of the water-supply should be carried out either by (*a*) the London County Council supplying its own area directly and supplying the outside authorities with water in bulk at a fixed price, or (*b*) that the London County Council should supply the area over which it has statutory rights and that the outside bodies should supply their own districts.

The London County Council had considered the question as to whether it was desirable that a new authority should be formed and invested with powers to carry out the water-supply of the county of London and the districts around, and they have come to the conclusion that such a solution of the question is undesirable; on the contrary, the London County Council were in favour of the immediate purchase by themselves of the property of the present companies supplying London with water. Mr. Cripps said he considered that Parliament had been in favour of the ultimate purchase of the undertakings of the companies by some one body. There were analogous cases also in provincial towns in which the water-supply which had at one time been in private hands had under Parliamentary sanction been taken over by the local authorities.

The Chairman asked if there were any statistical details with regard to the effect which these purchases had had on the cost of the water-supply in the case of these provincial towns but no information whatever on this subject was elicited.

In the case of London Mr. Cripps thought there were special reasons for the purchase of the water-supply by one authority. The reasons were briefly: 1. When the present companies for the supply of London with water were started

Digitized by Google

there was no protection for the consumer with regard to the management of the supply. 2. The poor did not know who supplied them except in the case of those amongst them who were able to read and who might see the form of application for the water-rate. [The Chairman asked for some more important reasons.] 3. There was no competition between the various water companies and although their authorised limits of supply overlapped they did not undersell one another. 4. London does not get its supply from a great distance, therefore no great expense is being incurred. [It was not apparent to the Chairman what force this reason had.] 5. The auditor of the accounts of the water companies was paid by the water companies themselves and in the case of legal expenses proceeding from the audit there was a case in which the auditor had to pay them out of his own pocket. [No details or particulars were given of this case.] 6. The different companies had various scales of charges. 7. The height to which the supplies were given was not the same in the case of all the companies.

The witness was unable to say whether the London County Council would be willing to go to arbitration with regard to the price at which the property of the companies should be bought, nor would he say what he thought would be a fair price for the Council to pay for the undertakings, nor would he say what price he thought the Council could afford to pay so as to enable them to carry on without pecuniary loss the various water businesses in the way in which they are conducted at present. In the course of examination the witness said that he regarded the interests of the City of London as not identical with the interests of the rest of London as far as the water-supply was concerned; indeed, they were adverse to those of the rest of London because of the much greater rateable value of premises in the City as compared with the number of the resident population.

The Chairman pointed out that he should have thought from the fact that as the rateable value of the City premises was very high it would be all the more to the advantage of the citizens to have a cheap supply of water.

The witness then explained that what he meant was that in the case of the City, where the quantity of water taken was not very great, and in the case of highly rated premises it would be to the advantage of consumers to pay for their water by meter—that is to say, according to the amount which they receive and not according to the value at which their premises are rated.

The meeting was adjourned shortly after 4 P.M. The next meeting will take place on Monday, Dec. 5th.

LEICESTER AND SMALL-POX.

(*Continued from p. 1342.*)

IT is important to note that Mr. Biggs in his evidence before the Royal Commission declared that the Leicester method had been perfected. This evidence was given in 1891, there having been no deaths from small-pox in Leicester for some years, and the outbreak of 1892-93 not having commenced. His words were: "That with the abandonment of vaccination and with the perfecting of the 'Leicester method' of sanitation, isolation, quarantine, disinfection, &c. during the last six years small-pox mortality becomes extinct." In cross-examination Mr. Biggs was asked by Lord Herschell (Q. 15729-30): "Have you gone into the question at all as to whether there has been a similar extinction of small-pox mortality in places in which your system of isolation and quarantine has not been adopted?" and "Would not an inquiry of that sort be essential to enable one to judge how far the particular result was due to the suggested cause?" In reply Mr. Biggs said: "The only inference I could deduce from a comparison of that kind would be this, that if a town which had practised vaccination had been found to be free from small-pox and a town which had left off vaccinating was equally free, then nothing could be claimed for vaccination." In the process by which he arrived at the statement that, of the quarantined, "133 were neither vaccinated nor re-vaccinated" we have already met with Mr. Biggs as a statistician. Here we have the honour of being introduced to him as a logician. Supposing we alter the subject matter slightly his answer will read as follows: "The only inference I could deduce from a comparison of that kind would be this, that if a town which had practised the Leicester method had been found free from small-pox and a town which had not practised the method was equally free, then nothing could be claimed for the Leicester method." We have much pleasure in making Mr. Biggs a gift of his own argument and in claiming him as a non-believer in the method. As a matter of fact, many places had had as little small-pox as Leicester during the years in which the method had been in vogue, and this was the case even if we exclude the outbreak of 1892-93. This being so, then according to Mr. Biggs "nothing could be claimed for the Leicester method." But in defiance of his own argument, small-pox being at zero in Leicester, Mr. Biggs is thoroughly persuaded of the value and perfection of the Method. In May, 1891, he wrote; "We find small-pox very easy to deal with, and the same hospital and staff of officials deal with small-pox as with other infectious diseases. There is no compulsion. If people choose they may go into quarantine, or they may stay out. No one's liberty is infringed."[1] It would appear, therefore, that the Leicester method, as described to the public and the Royal Commission by the Leicester antivaccinationists, consisted of notification, disinfection, quarantine, and isolation. In addition "general sanitation" is spoken of. The "note" of the system was its voluntary character. Compulsion was altogether repugnant to it. It was denied that there was even the indirect inducement of payment of wages during quarantine. Mr. Biggs's statement to the Commission was unequivocal: "I think there is sufficient evidence to prove that no compensation has been made in the shape of wages, and that all that has been done in carrying out our system has been to reimburse those whose articles of furniture have been destroyed." The hospital was there alike for such diseases as small-pox, scarlet fever, erysipelas, &c., and also for quarantine. It had the same staff of officials, and the same ambulance waggon for all diseases, the nurses being vaccinated or not as they pleased, and scarlet fever cases, vaccinated or unvaccinated being in one part of the hospital, and small-pox cases in another, and quarantined persons in another. The Jennerian "rite" was a dead letter. The liberty of the subject was strictly attended to. In short, the Leicester method had been perfected, and small-pox was non-existent. The Method, moreover, was alleged to have this great advantage, that it was good alike for all infectious diseases. Mr. Israel Hart, ex-mayor of the town, pointed this out to the Commission. As to small-pox he said: "I have no doubt you have heard that we have adopted such measures in the district that practically the disease is stamped out." As to other diseases, "if there is a case of fever it is dealt with directly, and there is no fear of an epidemic; epidemics, as we know, arise from contagion, and it is difficult for contagion to take place as contagious disease is dealt with at Leicester." To make sure of the matter Sir William Savory asked, "Your sanitary measures are effective, I presume, not only against small-pox, but against all forms of infectious disease?" and the answer was: "All forms of contagious disease." Truly a wonderful Method—and perfected.

In 1891, as we have said, Leicester was free from small-pox. In the three years, 1889, 1890, and 1891, not only had there been no deaths, but there had been no cases. In previous years there had been a few cases, but owing, as was alleged, to the method, the disease had not spread. The favourite expression was that small-pox had been "stamped out." It had not died out. In other places small-pox might have died out, but not in Leicester. There it had been killed—by the Method. Near the end of August, 1892, a tramp came to Leicester and developed a mild attack of small-pox, and so gave the method another opportunity of exhibiting its powers. The *Vaccination Inquirer* was naturally jubilant. It dealt with the subject in the same issue (November, 1892) which contained Mr. Biggs's article already referred to. "There has, it seems, been another importation of small-pox into Leicester, and again it has been stamped out without the disease getting any real hold. As usual, a tramp brought it into the town, and, being taken ill at a lodging-house, was removed to the workhouse. The precise details seem to be somewhat in dispute as to the way in which he managed to infect two others, both of whom had

[1] Vaccination Inquirer, 1891, p. 69.

Digitized by Google

severe attacks, one being fatal, the disease being in this case complicated with other disorders. The Leicester method, however, was equal to the emergency, and we hear nothing of the complaint spreading any further. We trust that the Commission will thoroughly investigate the circumstances of this latest Leicester success." Once more the Method had triumphed. The disease was again "stamped out." In accordance with the *Inquirer's* desire the Commission did investigate. What says their investigator, Dr. Coupland? That, instead of the disease having been stamped out, eleven cases were known of at the time the *Inquirer* was engaged in boasting about this "latest success." By the end of November there were sixteen more cases, all but perhaps two traceable to the tramp. This spread of the disease was something the *Inquirer* had not contemplated, and in its December issue it took a very curious line. Having already asserted that the "tramp" importation had been stamped out, it did not withdraw its misstatement, but declared that there had been an "importation of small-pox into the city on a rather larger scale than usual." But that was not all. Mr. Biggs, small-pox being absent, had told the Royal Commission that the Leicester system had been perfected. Now, small-pox being present and not having disappeared as before, the Leicester system came in for criticism, and the *Inquirer* urged that "public opinion should bring all the assistance it can to those of the Leicester authorities who are endeavouring to perfect the arrangements within the town for coping with epidemics of any kind, including small-pox." The authorities, or some of them (there seems an innuendo as to others), were thus "endeavouring to perfect" what had already been declared to the Commission to be perfected. Indeed, it now turned out that small-pox being abundantly present, and the "latest success" having been a desperate failure, criticisms of the Leicester system were rather welcome to the *Inquirer*, as providing it with an explanation of the outbreak, "so that every fault that can be found in the details and execution of the Leicester method, so far from being a proof that that method in itself is wrong, only shows the need for greater perfection *before the method itself can be said to have been really tried.*" (The italics are ours.) "Greater perfection" is a good phrase. It was only a Leicester town councillor who had told the Commission about the perfection of the Method, but a university graduate naturally wanted "greater perfection." Leicester had been free from small-pox for years. Anti-vaccinationist orators had stumped the country in glorification of what Leicester had done. Other towns had been strongly urged to copy its procedure. The Leicester case, the *Inquirer* had said, constituted "the keystone of the anti-vaccination arch." Now at last, however, when small-pox did begin to spread in Leicester the *Inquirer* was open to deny that the Leicester method had ever been really tried. If it were true that the Leicester hospital was only an old shed, as was being stated in THE LANCET, then that was no criticism of the Leicester system. Quite the contrary, "it is clear that so far the Leicester system has not broken down. It has not been tried."

The Leicester Method, in fact, was to be looked on as resembling Sairey Gamp's Mrs. Harris. There never had been any Mrs. Harris and there never had been any Method. So long as there had been no spread of small-pox in Leicester there had been plenty of talk in the *Inquirer* and before the Royal Commission and in letters to newspapers, but the talk had been about a myth, or at best a theory, and the journal which only the month before had been boasting of a fresh triumph of the Method was now preparing to take up the position that there "really" never had been anything more than talk. For a parallel to this attitude we have to look to anti-vaccination itself. When Gloucester was free from small-pox whilst neglecting vaccination it was declared to be a very sanitary town and to owe its freedom to sanitation. When small-pox came the town was forthwith denounced as highly insanitary and the denunciations have ever since formed the standing defence of Gloucester anti-vaccinationists.

The question for the *Inquirer* now was, whether it should in its next issue (for January) advance further on the line adopted in December and denounce Leicester for its want of a Method, or retrace its own steps and re-adopt the November attitude—that there really was a Method and that the Method was triumphant. The course of the outbreak during December might decide the matter. In the first half of the month there were nine or ten cases, and then suddenly there was a cessation of notifications, only one more being received previously to Dec. 30th. This lull seems to have settled the question, for on Jan. 2nd the *Inquirer* declared "that the Leicester system has again triumphed without recourse to vaccination or any other measures other than those always included in the Leicester method." The "old shed" of a hospital remained, but small-pox was fondly supposed to have gone. Radical change of attitude was hardly possible after this even for the *Inquirer*, and thirty-six cases having been notified in January, the editor tried to console himself and his readers by telling them in February, not that the Method was still triumphant, but that there were well-vaccinated places that were no better off than Leicester as regards small-pox. What a pitiful declension—that Leicester with its wonderful Method had no more small-pox than places that had trusted to the despised method of the much reviled Jenner! And what a contrast with the claim of Mr. Biggs before the Commission: "Your contention is, that whatever the virtue of vaccination in preventing small-pox, this good system of sanitation has just as much virtue?—My contention is that it has far more and that, in fact, vaccination has none, because we have dealt with small-pox without vaccination." (Q 15,734.) Then in March the *Inquirer* wrote that its readers would "hear with mingled surprise and pleasure that there are still some people left alive in Leicester." And here we shall leave the *Inquirer* to enjoy its mingled surprise and pleasure at the success of the Method, not even waiting to discuss which might be the greater—its surprise or its pleasure.

(To be continued.)

MAYORAL HONOURS FOR MEDICAL MEN.

BOOTLE.

JOHN MCMURRAY, M.D., M.S., M.A.O.R.U.I., matriculated in the Queen's University, Ireland, in 1878, and passed all his examinations for his profession with honours. He was a prizeman in various subjects, and competed for and held the Senior Scholarship in Therapeutics and Pathology (1881-82). He also obtained a gold medal given at the Children's Hospital, Belfast. After graduating Dr. McMurray acted as assistant for three months when he obtained the appointment of junior house surgeon at the East Dispensary, Liverpool. About a year after he was promoted to the position of senior house surgeon at the North Dispensary, Liverpool. From there he went to the Liverpool Parish Infirmary, became senior house surgeon within twelve months, and remained in that institution for almost three years. The appointment of medical officer to the Kirkdale Industrial Schools having become vacant he obtained this post and also the position of medical officer to two branch establishments of the Liverpool Workhouse. In February, 1888, he commenced private practice in Bootle, and in 1892 he was invited to become a member of the Bootle School Board. In 1895 he obtained a seat on the Stanley Ward Council. As a councillor for that ward he served on the Health, Library and Museum, and Parks and Baths Committees, and was this year unanimously elected by the council as mayor of the borough.

CARNARVON.

Robert Parry, M.B., L.R.C.P. Lond., M.R.C.S. Eng., L.S.A., studied during the years 1872-74 at Owens College, where he passed the Matriculation and Preliminary Science Examinations of the University of London. In October, 1874, he entered Guy's Hospital and gained the first prize at the end of the session. Having filled the usual appointments, he passed the M.R.C.S. Eng., and L.S.A. examinations, and commenced practice at Harlech, where he remained for a few months. He returned to London in 1880 as assistant medical officer to the Cleveland-street Asylum and then passed the M.B. Lond. and L.R.C.P. Lond. He remained in Cleveland-street till 1883, when he started practice in Carnarvon. He entered the town council in 1887, and has since with the exception of one year been a member. Dr. Parry has served on the sanitary and other committees of the council, and for the last five years has been chairman of the Gas Committee. In 1894-95 he acted as deputy-mayor.

Digitized by Google

COVENTRY.

Thomas Webb Fowler, M.R.C.S. Eng., L.R.C.P. Lond., L.S.A., was born at High Wycombe, Buckinghamshire, in 1861. He received his early education at Elmfield College, York, and afterwards studied at Queen's College, Birmingham, where he obtained honours certificates in physiology. He commenced practice in Coventry in 1885 and first entered the city council as a Conservative representative for Spon-street Ward at a by-election in August, 1889. In the following year, owing to the extension of the city boundary, the whole of the councillors vacated their seats; Mr. Webb Fowler again fought Spon-street Ward and has not since that period had to fight for his seat. Upon entering the council he first served upon the Gas Committee, and subsequently upon the Estates and Finance, Sanitary, and General Works Committees. He is on the Sanitary Committee and has occupied the position of vice-chairman of the Water-works Committee and of the Electric Light Committee since its inception. In sanitary matters Mr. Fowler has occupied a prominent position. As an example of the esteem in which the new mayor is held by the people it may be mentioned that on one occasion when the police were being pelted by a portion of the public at the Market Hall in connexion with an endeavour to sell goods seized for non-payment of the vicar's rate he mounted a form near the Market Hall, addressed the crowd for a few minutes, and succeeded in quelling the turbulence.

HASTINGS.

Frederic Bagshawe, M.D. Cantab., F.R.C.P. Lond., belongs to an old family of the Peak of Derbyshire. His grandfather was Sir William Bagshawe. Dr. Bagshawe was educated at Uppingham and thence proceeded to St. John's College, Cambridge, where he graduated and became M.A. in 1861 and M.D. in 1865. He studied medicine at Cambridge and at St. George's Hospital, London, became M.R.C.P. in 1864, and was elected F.R.C.P. in 1879. He held a medical appointment at the Hospital for Sick Children, Great Ormond-street and became a colleague of Sir William Broadbent as physician to the Great Western Dispensary, London. He began to practise in Hastings in 1865, but spent the winter seasons practising on the Riviera up to the time of the Franco-German War in 1870, when he finally settled in Hastings. He became assistant physician to the East Sussex, Hastings, and St. Leonards Hospital in 1871, and later full physician. For twelve years he was engaged with Mr. Howell and others in trying to secure a new site whereon to rebuild the hospital, the majority of governors voting being in favour of removal. He was chairman of the south-eastern branch of the British Medical Association in 1883, and presided over one of the sections of the Health Congress held in Hastings in 1889. He has taken an active interest in the water-supply and sanitary questions of the borough. Quite recently he has been placed on the county bench of magistrates.

HEDON (HULL).

James Soutter, L.R.C.P. Lond., M.R.C.S. Eng., L.S.A., who is thirty-four years of age, was a pupil of Mr. R. H. Bouchier Nicholson for two years and attended the practice of the Hull Royal Infirmary. The rest of his education he received at St. Bartholomew's Hospital, subsequently qualifying as M.R.C.S. Eng., L.R.C.P. Lond., L.S.A. He settled in Hull and was extra-mural house surgeon to the Children's Hospital, but on a death vacancy occurring in his native town he bought the practice ten years ago. His family have been connected with the borough a good many years, his great-grandfather having been a former mayor. He has been a town councillor since 1890, and was the mayor last year. He is a Surgeon-Captain in the 2nd East Riding Yorkshire Volunteer Artillery, Surgeon to H.M. troops stationed at Paull Point Battery, and district medical officer to part of two unions—viz., Skirlaugh and Patrington.

HENLEY-ON-THAMES.

James Lidderdale, M.R.C.S. Eng., L.S.A., entered as a student at St. Mary's Hospital in 1868, being then eighteen years old. In 1870 he was appointed assistant demonstrator of anatomy in the medical school and also a prosector at the Royal College of Surgeons of England owing to the excellence of his work. This latter appointment led to his being given the office of assistant curator to the Hunterian Museum of the College, and assistant to the Court of Examiners of the same College, which he held for three years—viz., from 1870 to 1873. He qualified as M.R.C.S. Eng. in 1872. Subsequently he was appointed resident medical superintendent to the Female Lock Hospital, Harrow-road, which appointment he held for some time. In 1874 he left London to practise in the country at the request of his family, and held various union and other similar appointments until the end of 1890, when he went to Henley to practise in partnership with Dr. Allden and Dr. Smith. In 1893, at the request of a large number of the ratepayers of the borough, he was nominated as a candidate for the town council and was returned at the head of the poll without soliciting a single vote. Last year he was re-elected without opposition. While on the council he has been a member of the Drainage Committee in connexion with the new drainage scheme which has been successfully carried out. Latterly he has been chairman of the General Purposes Committee and has now been elected mayor of the borough having just completed the fourth year of office as a councillor.

MARLBOROUGH.

James Blake Maurice, M.D. St. And., F.R.C.S. Eng., is a Justice of the Peace for Wiltshire, and Surgeon to the Savernake Cottage Hospital, Medical Officer to the Somerset Hospital, Froxfield, and Surgeon to the Great Western Railway Provident Society.

PRESTON.

John Edward Dunn, M.R.C.S. Eng., L.R.C.P. Edin., was educated at the Preston Grammar School and was subsequently a pupil for five years of the late Dr. Wm. Smith, of Preston. For four years he studied at St. Thomas's Hospital, London, and has been in busy and active practice since qualifying. He is medical officer of the No. 6 district Preston Union and Public Vaccinator of the No. 1 district. Mr. Dunn is an ex-president of the Preston Medico-Ethical Society.

RUTHIN.

Job Medwyn Hughes, M.B., C.M. Edin., graduated in 1886. For six years he has held the appointment of medical officer of health for Ruthin rural district, and was put on the Commission of the Peace for the county of Denbigh in 1893. In 1892-93 he was appointed mayor, and has this year received the same honour.

SALTASH.

Robert Thornton Meadows, M.D., M.S. Edin., is the son of Surgeon-Major-General R. W. Meadows, retired. He studied at Edinburgh University and took the degrees of M.B., C.M. in 1885. After a trip abroad he started practice at Saltash, Cornwall, in March, 1887. He took the degree of M.D. Edin. in 1892 and D.P.H. Lond. in 1894. For several years Dr. Meadows was the medical officer of health to the Saltash Urban Sanitary Authority and has showed great energy in coping with small-pox. On Nov. 9th, 1897, he was unanimously elected mayor of the borough and J.P. for the county of Cornwall. Dr. Meadows, who is thirty-five years of age, is Surgeon-Captain 2nd Volunteer Battalion Duke of Cornwall's Light Infantry and holds the same rank in the Army Medical Reserve of Officers.

The following member of the dental profession has been elected Mayor of

CHELTENHAM.

Richard Rogers, L.D.S. Irel., re-elected Mayor of Cheltenham for the third time.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE thirteenth annual meeting of the Fellows and Members of the Royal College of Surgeons of England was held on Nov. 18th, the President, Sir WILLIAM MAC CORMAC, Bart., taking the chair; twenty-eight Fellows (including seventeen Members of Council) and fifty-five Members were present.

The PRESIDENT welcomed the Fellows and Members present saing he had unfortunately been absent last year from causes beyond his control, and in placing before the meeting the report of the Council for the year ending July 8th, 1897, mentioned that many subjects of great

Digitized by Google

importance were dealt with in the report. For instance, on page 4 an account was given of the endeavour which the Council had made to ascertain the opinion of the Fellows on the question of the desirability of according to the Members of the College direct representation on the Council. An elucidatory statement had been prepared and the Fellows were requested to give their opinion on the direct representation of the Members and on the way in which it should be effected. On page 11 was an account of the action taken by the Council in the matter of the great prevalence of venereal disease among the British troops in India; they had sent an address to the Secretary of State for India pointing out the danger it threatened both to the army itself and to the nation. The Council had been informed by the Secretary of State for India that their opinion had proved of much value to him. A portrait of Lord Lister had been presented to the College, and the honorary medal had been awarded to Lord Lister and to Sir James Paget. The reconstruction of the lecture theatre had greatly increased the comfort of the seats. The museum and the library had been fully maintained, and the latter had been visited by more than 10 000 readers. During the year many who had held official positions in the College had been removed by death, and among them might be mentioned Sir John Eric Erichsen, Sir George Humphry, Sir Spencer Wells, Mr. Walter Rivington, and Mr. Oliver Pemberton, and they had also to regret the loss of their librarian, Mr. Bailey. With regard to the motions to be brought before the meeting he thought it advisable to say a few words. The sentence in the first resolution that "parts of the elucidatory statement are misleading" was not a matter of fact but a matter of opinion and therefore he would ask the mover and seconder of that resolution to insert the words "in the opinion of this meeting." As to the second resolution he would like to point out that the Council was certainly the only representative body in the College and therefore it must represent the Members as well as the Fellows. With regard to the third resolution he would say that medical aid associations vary very greatly in character and constitution, and therefore the Council after careful consideration had declined to lay down any general rule, but had expressed their willingness to decide on any individual case submitted to them.

Dr. THOMAS MORTON then rose to move the first resolution which, with the alteration suggested by the President, read as follows:—

That as in the opinion of this meeting parts of the "Elucidatory Statement" are misleading and do not adequately represent the facts which were further obscured by a circular issued under the auspices of a member of the Council the recent vote on Members' representation cannot be regarded as a satisfactory or final expression of opinion by the Fellows.

He disclaimed any wish to impute any intention to mislead to any individual member of the Council in the preparation of the elucidatory statement, but he would show that it was misleading. When the result of the voting was announced the Society of Members applied to the Council for a special meeting, but as the Council had declined to call such a meeting this was the first opportunity Members had had of bringing the subject forward. He felt sure that if the questions to the Fellows had been put in a fairer way the result would have been different. He pointed out that the intentions of the Members in applying for representation occupied only eleven lines, while the reply of the Council occupied twenty-six. In Section 3 it appeared as if Members were standing out for representation by Members only, but this claim had been distinctly given up when the deputation from the Society of Members met a committee of the Council. The letter mentioned in Section 3 was not quoted in full and so its meaning was apparently altered. Dr. Morton considered that the rule for the Council of the College should be that which was the rule for the General Medical Council—namely, that any Member of the College should be eligible for the Council of the College apart from his academical status. The College depended greatly on its Members for its income, and it was not fair to estimate the share contributed by the Members in the way this had been done in the circular. The College was not a trading body and its object in its accounts was not to show as large a balance as possible. It was quite true that the primary object of the College was the encouragement of the science and art of surgery, but it was, as Mr. Hutchinson had said, impossible for the College to separate itself from many questions which might be called political, and this was shown by the fact that many of the subjects dealt with in the report before the meeting were in no way associated with lofty science but were connected with important social questions of the day. The Members had an inherent right to representation and this could not be controverted by proving that they had no legal right; the Members as well as the Fellows were the lineal descendants of the members of the old Company of Surgeons and their right would be recognised in time. The admission of the Members to a share in the representation on the Council of the College would certainly benefit the College itself.

Mr. JOSEPH SMITH seconded the motion and contended that the elucidatory circular was utterly misleading.

Sir ROBERT CRAVEN mentioned that he had voted in favour of allowing the Members to be represented on the Council; but the adverse vote of the Fellows had made it necessary that a new charter should be obtained. Therefore he advised the Members to turn their attention to that.

Mr. W. G. DICKINSON asked that the names of those Fellows who had voted in favour of the representation of the Members should be published.

Mr. HENRY MORRIS congratulated the mover of the resolution on the very temperate tone of his speech and said that though he had always opposed the claims of the Members yet it had been his wish and the wish of every member of the Council to send to the Fellows an unbiased elucidatory statement, and he mentioned that there had been on the committee appointed to draw up that statement two consistent supporters of the claims of the Members. Most of the arguments in the circular advanced on behalf of the Members were taken from communications received from the Society of Members, and especially was that true of Section 3 to which reference had been made.

Mr. W. G DICKINSON said that he had written the letter which was quoted in the elucidatory statement, and his meaning had been that the Society of Members, though willing to be represented by Fellows, were of opinion that every member of the body corporate should be eligible.

The PRESIDENT then put the resolution to the meeting, and 31 voted in its favour and 1 against, and the resolution was declared to be carried.

Mr. GEORGE BROWN then moved the second resolution which was as follows:

That this meeting repudiates the claim put forward by the Council in its resolution of March, 1896, to represent "the Members as well as the Fellows," and again calls upon it to accord the franchise to the former.

He remarked that possibly the subject of the first resolution might be considered a matter of opinion, but this was a question of fact. The claim that the Council represented the Members as well as the Fellows was utterly baseless; perhaps it was intended to be facetious. The Council was elected by the Fellows only, so how could it represent the Members? Mr. Jonathan Hutchinson had said, "Do not the Members possess a moral right to representation on the Council—that is, a right founded upon justice? If an entirely new scheme were to be devised for the government of such a body as the College now is, with its thousands of Members and hundreds of Fellows, can anyone believe that the former would be wholly excluded from power?" He did not think that the representation of the Members would materially alter the constitution of the Council.

Dr. HERBERT SNOW seconded the resolution and compared the Members to taxpayers who were not allowed to vote; for the Members contributed more than £14,000 out of £25,000, which was the total annual income of the College.

Dr. WARD COUSINS pointed out that the resolution of the Council against which Mr. George Brown's motion was directed was by no means unanimous, for though 11 had voted in its favour 8 had voted against it.

Surgeon-Major INCE considered that the Members were on the high-road to obtaining representation on the Council. He thought it would be wise to extend the franchise to Members of twenty years' standing. He believed he was correct in saying that the majority of the Fellows were in general practice. On being put to the meeting the resolution was carried by 37 votes to 1.

Mr. W. G. DICKINSON moved the third resolution:

That this meeting, in view of the widespread public and professional evils induced by "Medical Aid Associations" and other companies trading in medical attendance, calls upon the Council to make a clear pronouncement for the information of Fellows and Members that the acting by qualified medical practitioners as the paid officials of any institutions which tout and canvass for patients or which allow the well-to-do classes to take advantage of rates of payment arranged to meet the necessities of the poor is "disgraceful in a professional respect" and deserving of censure.

Digitized by Google

He said he hoped that this motion would meet with more sympathy from the Council as it was not in any way in opposition to the Council. The matter was of the greatest importance; the harm done to medical practitioners by medical aid associations was incalculable, and this in conjunction with the overcrowded state of the profession was rendering the condition of the general practitioner unbearable. Then there was the very important consultation question. He did not on the whole object to the decision of the Council refusing to prohibit consultations with the practitioners serving under the medical aid associations, because the matter had to be looked at from the point of view of the public as well as from the point of view of the profession, but he considered that consultants would be less willing to give their services than they are if the College would speak definitely on the subject. The decisions contained on page 13 of the report were not what was wanted. In 1893 the Royal College of Physicians of Ireland expressed its disapproval of its Licentiates accepting appointments to medical aid associations. A case had occurred recently in which the medical man, a Licentiate of the Royal College of Surgeons in Ireland, attached to a medical aid association had resigned on receiving from his College a letter pointing out the impropriety of his holding such a post. In 1888 the Royal College of Physicians of London had declared it to be undesirable that any Fellow or Member of that College should hold a post in an association for treating patients for profit; but it would have been of more value if this resolution had applied also to their Licentiates.

Mr. BRINDLEY JAMES seconded the resolution and said that the lot of the general practitioner was very hard; his patients were taken from him by the medical aid associations, by the hospitals, and by the consultants.

Dr. BEVERLEY (of Norwich) said he was deputed by his professional brethren to thank the council for the action they had taken as mentioned on page 13 of the report, but also to express the great dissatisfaction they felt at the reply, for if the By-laws did not permit the Council to abate such evils as those described, then the By-laws must be altered.

Dr. ALDERSON considered the resolution of great importance to general practitioners; even such clubs as the Foresters did a great deal of harm.

Mr. MOXON (of Yarmouth) said the Council had expressed its sympathy with those who were injured by these trading associations; but they wanted more than sympathy, they wanted a clear pronouncement that the Council disapproved of this "sweating" of medical men.

Mr. GEORGE BROWN considered that it was clearly a matter of discipline; in the case already referred to, when a graduate of the College of Surgeons of Ireland had resigned on receiving the opinion of the College on his conduct, the medical aid association had been stopped. Why should not the College of Surgeons of England do what had been done by the College of Surgeons of Ireland?

Mr. ALFRED WILLETT asked that specific instances of the action of its members should be brought to the notice of the Council of the College. From beginning to end the Council had never had brought to its notice the conduct of any individual; the complaints had always been in general terms.

Surgeon-Major INCE said canvassing for patients was legal and could not be stopped.

The PRESIDENT before putting the resolution to the meeting said that the Council was very anxious to do its utmost in the matter, but it was useless merely to express a pious opinion; if a particular instance of canvassing for patients were brought to its notice with satisfactory evidence the Council would consider the case carefully.

The motion was carried and with a vote of thanks to Sir William Mac Cormac for presiding the meeting dissolved.

WATER-SUPPLY OF SALISBURY.—The Salisbury sanitary authority have recently submitted samples of the water-supply of that city for analysis. The analyst reports the supply of the city proper to be good and that of the Close fair; but he condemns the Wyndham-park district supply on the ground that it is contaminated with sewage. This is supposed to be owing to defective water-closet fittings, and consequently on Nov. 19th the sanitary authority cut off the water-supply at all houses where the existence of bad fittings made possible a communication between the soil pipes and the water service. Until these defects are remedied the inhabitants of these houses will be supplied from stand-pipes in the streets of the district.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Derbyshire County District.—The registration county of Derbyshire is not the administrative county presided over by the county council, and hence the valuable statistics of the former are not applicable to the latter. Dr. Sidney Barwise trusts that the necessary modifications will soon be effected, and that when the time for the 1901 census arrives there will be but one Derbyshire. There seems in the case of this county to be no serious difficulty in the way. Out of the population of the county no less than 95 per cent. are under the protection of the Notification Diseases Act, and Dr. Barwise thinks that the remaining 5 per cent. will remain obdurate until the Act is made compulsory. Among what may be the recalcitrant authorities we note with astonishment that of Matlock. The subject of infantile mortality is being attacked in a very practical manner by the people of Chesterfield, who have engaged a trained nurse to visit all houses in which births have recently occurred and there to offer advice as to the feeding and general management of infants. The nurse obtains each week from the registrar a copy of the births registered. In advocating greater stringency with regard to dairies, cowsheds, and milkshops Dr. Barwise refers to the excellent example set by the Corporation of Manchester, who, in advertising for tenders for milk, state that preference will be given to those who undertake that the milk shall be derived from cows which have been examined and tested by the tuberculin test by officers appointed by the corporation. This is certainly a decided step in the right direction. But little reference is made in the district reports as to the Factories and Workshops Act of 1895, and Dr. Barwise thinks that the Act will not be thoroughly enforced until local medical officers of health have proper security of tenure. The prevention of rivers' pollution in Derbyshire is making steady progress; but in several instances there is difficulty in arriving at the best means of sewage treatment. In connexion with this subject of the purification of sewage Dr. Barwise has prepared a special report which should be of much use to members of local bodies who are endeavouring to make themselves familiar with the questions upon which they are in large part called upon to decide.

Oldham Sanitary District.—During 1896 Oldham added a small-pox hospital to its equipment, and we may reasonably hope that no more will be heard of the baneful influence of the Westhulme Hospital when cases of small-pox were treated in it. Doubtless Dr. Niven, of Manchester, will read with satisfaction of this improvement in the district over which he formerly presided. Typhus fever is not yet extinct in Oldham, and last year there was a localised outbreak of this disease. There were seven cases and two deaths, one of the deaths, we are sorry to see, being that of a nurse who had attended upon the sick. Mr. Tattersall is far from being satisfied with the manner in which the notification of puerperal fever is carried out, and he states that in his own district no cases are reported unless death occurs or is thought to be likely to occur. Smoke abatement in Oldham has made some progress recently, and Mr. Tattersall tells us that there are fewer offenders now that the limit for black smoke is four minutes per half-hour than there were when this limit was nine minutes per hour. He thinks that if the limit was still further diminished the manufacturers would be capable of meeting it.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6744 births and 3927 deaths were registered during the week ending Nov. 20th. The annual rate of mortality in these towns, which had increased in the four preceding weeks from 16·9 to 19 0 per 1000, declined again last week to 18·6. In London the rate was 18·9 per 1000, while it averaged 18·4 in the thirty-two provincial towns. The lowest death-rates in these towns were 11·3 in Bradford, 13·4 in Portsmouth, 13·8 in Croydon, and 13·9 in Plymouth; the highest

Digitized by Google

rates were 21·3 in Sunderland, 22·1 in Burnley, 24·3 in Liverpool, and 24·7 in Leeds. The 3927 deaths included 462 which were referred to the principal zymotic diseases, against 412 and 461 in the two preceding weeks; of these, 159 resulted from measles, 67 from "fever" (principally enteric), 64 from diphtheria, 63 from whooping-cough, 52 from diarrhœa, and 1 from small-pox. The lowest death-rates from these diseases were recorded in Brighton, Plymouth, Preston, and Bradford, and the highest rates in Gateshead, Burnley, Halifax, and Blackburn. The greatest mortality from measles occurred in Burnley, Blackburn, and Halifax; from scarlet fever in Derby and Halifax; from whooping-cough in Newcastle-on-Tyne; from "fever" in Derby, Salford, and Huddersfield; and from diarrhœa in Gateshead. The 64 deaths from diphtheria included 37 in London, 6 in Liverpool, and 3 in Wolverhampton. One fatal case of small-pox was registered in Bristol, but not one in any other of the thirty-three large towns; and no small-pox patients were under treatment in any of the Metropolitan Asylum Hospitals. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of last week was 3792, against 3652, 3680, and 3777 on the three preceding Saturdays; 397 new cases were admitted during the week, against 416, 339, and 460, in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 363 and 420 in the two preceding weeks, declined last week to 414, and were 12 below the average. The causes of 47, or 1·2 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bradford, Leeds, Newcastle-upon-Tyne, and in eleven other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Salford, Blackburn, and Halifax.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18·8 and 20·1 per 1000 in the two preceding weeks, declined again to 18·5 during the week ending Nov. 20th, and was slightly below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 16·6 in Dundee and 17·3 in Leith to 21·5 in Aberdeen and 22·1 in Perth. The 552 deaths in these towns included 19 which were referred to diarrhœa, 12 to measles, 10 to whooping-cough, 9 to "fever," 8 to scarlet fever, and 4 to diphtheria. In all, 62 deaths resulted from these principal zymotic diseases, against 70 and 64 in the two preceding weeks. These 62 deaths were equal to an annual rate of 2·1 per 1000, which was slightly below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 12 and 7 in the two preceding weeks, rose again to 12 last week, of which 7 occurred in Glasgow and 5 in Greenock. The 10 deaths from whooping-cough showed a slight further decline from those recorded in recent weeks, and included 9 in Glasgow. The deaths referred to different forms of "fever" which had declined from 13 to 4 in the four preceding weeks, rose again to 9 last week, of which 8 occurred in Glasgow. The fatal cases of scarlet fever, which had been 18 and 11 in the two preceding weeks, further declined to 8 last week, and included 4 in Edinburgh, and 2 in Glasgow. Of the 4 deaths from diphtheria, 2 were recorded in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 142 and 161 in the two preceding weeks, declined again to 145 last week, and were 34 below the number in the corresponding week of last year. The causes of 36, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had declined in the three preceding weeks from 28·2 to 19·8 per 1000, rose again to 23·3 during the week ending Nov. 20th. During the past seven weeks of the current quarter the death-rate in the city has averaged 22·8 per 1000, the rate during the same period being 17·6 in London and 18·6 in Edinburgh. The 156 deaths registered in Dublin last week showed an increase of 23 upon the number in the preceding week, and included 10 which were referred to the principal zymotic diseases, against 12 and 24 in the two preceding weeks; of these, 6 resulted from "fever," 2 from diarrhœa, 1 from scarlet fever, and 1 from diphtheria, but not one either from small-pox, measles, or whooping-cough. These 10 deaths were equal to an annual rate of 1·5 per 1000, the zymotic death-rate during the same period being 2·4 in London and 2·7 in Edinburgh. The deaths referred to different forms of "fever," which had been 8 and 10 in the two preceding weeks, declined again to 6 last week. The mortality from scarlet fever showed a marked decline, while the mortality from diphtheria corresponded with that recorded in the preceding week. The 156 deaths in Dublin last week included 33 of infants under one year of age and 38 of persons aged upwards of sixty years; the deaths of infants showed a marked increase, while those of elderly persons were slightly below those recorded in the preceding week. Eleven inquest cases and 8 deaths from violence were registered; and 46, or nearly a third, of the deaths occurred in public institutions. The causes of 12, or nearly 8 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-MAJOR TIDBURY, M.D., has assumed Charge of the Station Hospital and troops at Winchester.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Colonel Bainbridge to be Surgeon-Major-General, vice Surgeon-Major-General Cook, deceased. Surgeon-Lieutenant-Colonel Arthur Tomes (Bengal) and Surgeon-Major Framji Ruttonji Divecha, 8th Regiment of Madras Infantry, retire from the service subject to Her Majesty's approval. Surgeon-Lieutenant-Colonel Martin, Civil Surgeon, who has been permitted by Her Majesty's Secretary of State for India to return to duty before the expiry of the leave granted him, is posted to the Hoshangabad District.

NAVAL MEDICAL SERVICE.

The following appointments have been announced:—Staff-Surgeons: Samuel W. Johnson to the *Liffey;* Samuel Keays to the *Devastation;* and Joseph R. M'Donnell to the *Trafalgar.*

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain Thomas Lyndon, M.D., having resigned his Volunteer appointment, ceases to belong to the Army Medical Reserve of Officers.

VOLUNTEER CORPS.

Artillery: 2nd East Riding of Yorkshire (Western Division, Royal Artillery): Surgeon-Lieutenant H. Robinson, M.B., to be Surgeon-Captain. *Royal Engineers* (Volunteers): 1st Middlesex: Henry Macnaughton Macnaughton-Jones, M.B., to be Surgeon-Lieutenant. *Rifle:* 4th Volunteer Battalion the King's (Liverpool Regiment): Surgeon-Major W. J. Fleetwood, M.D., to be Surgeon-Lieutenant-Colonel.

THE HEALTH OF THE RUSSIAN ARMY.

The report of the Russian Army Medical Department which deals with the health of the army during the year 1895 was recently issued and contains a large number of statistics of some interest. The average strength of the Russian Army in that year was rather over a million officers and men, the former numbering 40,356, the latter 981,256. Among the officers the percentage of attacks of sickness was 50·8, and the death-rate 0·64 (a death-rate, therefore, of 6·4 per 1000). Among the men the admissions to hospital were at the rate of 32·8 per cent. of the total strength, while the sick cases treated as out-patients were 175·8 per cent. The total sickness, rate was therefore 208·6 per cent., which is equivalent to saying that each soldier was reported sick more than twice in the year. This is slightly above the percentages of the last five years, which have been respectively 179·8, 183·8, 194·4, 207·3, and 200·8. The number of men incapacitated by sickness was 2·4 per cent. of the total strength and the total loss to the army by sickness and death was about 3 per cent. Among individual groups of diseases infectious disorders occupied the first place (69,850 treated in hospital) and diseases of respiratory organs the second (42,928 cases in hospital). There were 33,735 cases of venereal

Digitized by Google

disease admitted to hospital. Diseases of the respiratory organs caused a greater loss of strength to the army than any others; they affected 34·2 per cent. of the total number incapacitated by disease. Of the different divisions of the army those who suffered most were the prisoners in military prisons. Their attack-rate (80 8 per cent. of total strength treated in hospital) and death-rate (1·8 per cent) were treble the average for the whole army. This seems to point to sanitary defects in Russian military prisons. The following table is worth quoting:—

Branch of service.	Percentage of Sickness.*	Percentage of Deaths.	Incapacitated.
Infantry	36·6	0·64	2·60
Artillery	29·5	0 61	2·20
Cavalry	27·9	0 60	2 36
Engineers	27·2	0·57	2·40
Cossacks	27·1	0·47	1·90
All others	37·7	0·47	2·00

* Cases treated in hospital are alone considered in this column.

From these figures it appears that the Cossacks are the healthiest branch of the service and the infantry and others not specified the least healthy. The superior health of the Cossacks is further shown by the fact that the minimum total sickness-rate (including in- and out-patients) of the territorial divisions of the army occurred in the Don Cossack Province, where the rate was only 115·4 per cent. (the rate for the whole army being 208·6 per cent.). The highest sickness-rate was in Transcaspia, where it reached the high figure of 327·5 per cent. In St. Petersburg it was also high (271 per cent.). The highest death-rate was also in Transcaspia (0·98 per cent.), and the lowest in the Amur region (0·29 per cent.). Cholera occurred in the army only in the Kief district, where there were 344 cases and 94 deaths.

THE ROYAL NAVY LIST PUBLICATIONS.

Lean's Royal Navy List, published quarterly by Messrs. Witherby and Co., High Holborn, the October issue of which has reached us, deserves all the praise that has been bestowed upon it. To the Naval profession, the Press, and, indeed, to everyone who takes an interest in our first line of defence, it is an indispensable work of reference.

The Royal Navy List Diary and Naval Handbook for 1898 is a new publication issued by the same publishers, price 3*s*. The contents include a Summary of the Year's Naval Progress, by Professor J. K. Laughton, M.A., F.R G S.; the Navy Estimates for 1897–98, with Full Statistical and Comparative Tables; a Calendar of Notable Naval Events; the Naval Honours and Obituary for the Year, with the War and Meritorious Services of Deceased Officers; a Full Account of the Celestial Phenomena for 1898, with Notes and Tables of Tides, and Monthly Astronomical Ephemeris; Original Descriptive Articles on the Tides and Terrestrial Magnetism; Table of Stamp Duties and Fees; the Night Signals of the Principal Lines (revised to date); and a diary (a whole page to a day) with all the usual tables found in diaries. That the new venture will be a success there can be no doubt for such a book has long been wanted and the editors are to be congratulated upon the result of their labours.

VOLUNTEER AMBULANCE SCHOOL OF INSTRUCTION.

The twenty-first distribution of prizes will take place at St. Martin's Town Hall, W.C., on Dec. 9th, at 8.30 P.M., when Major-General H. Trotter will preside. There will also be a Bohemian Entertainment.

THE Hackney Vestry decided at their last meeting (on the 17th inst.) to appoint a lady sanitary inspector whose special duty it would be to look after the sanitary conditions of the workshops, workrooms, laundries, &c., where women and girls are employed.

MUNICIPAL MATTERS IN CARDIFF. — Dr. T. Wallace, J.P., has been re-elected on the free library committee of the Cardiff Corporation. Mr. J. L. Treharne, M.R.C S. Eng., L.S.A., J.P., and Mr. A. Rees, L.R.C.P. Lond., M.R.C.S. Eng., have been placed upon the technical committee of the town council, and Dr. C. T. Vachell, J.P., has been elected upon the museum committee.

Correspondence.

"Audi alteram partem."

"DR. R. R. RENTOUL'S RESIGNATION OF MEMBERSHIP OF THE GENERAL MEDICAL COUNCIL."

To the Editors of THE LANCET.

SIRS,—Dr. Rentoul's manifesto to his late constituents, of whom I was one, enables the other side to be heard. I am strongly of opinion that Dr. Rentoul's return last December at the head of the poll was out of gratitude for past services and by no means because his constituents considered him the best direct representative of their interest on the General Medical Council. I know several who voted for him and while they admired his courage they disliked his methods and many of his supporters resented his contemptuous style of addressing his fellow practitioners. He is deficient in the *suaviter in modo*, and there never was a time in which this quality was in such demand as at present. Let us come to the point.

Dr. Rentoul says: "I resigned as I came to the finding that I could not accomplish any of my work as a member of the Council constituted and worked as it now is."[1] It is unnecessary to say that Dr. Rentoul knew all about this before he became a candidate, so that this reason falls to the ground. He is considered a fool who proceeds to build a house without counting the cost. Was it "honest" to undertake the duties which he admits in Paragraph 2 he was unable to fulfil? A second, although it is called the "first," reason in the text is advanced — viz., the loss of confidence, or what he calls the "desertion," of his constituents. What does Dr. Rentoul advance in support of this assertion? Why, of course, that his Bill for the Registration of Midwifery and other Nurses was ignored by 126 out of 129 medical societies to which he sent it. To a "practical" man this fact would suffice to demonstrate the impracticability of the Bill I drafted a Bill entitled, "The Sick and Obstetric Nurses' Bill," an outline of which appeared in THE LANCET before Dr. Rentoul's Bill was heard of, and MS. copies were sent on request to Mr. Skewes-Cox, M.P. (our local member) and the Midwives' Registration Society. I may have it printed before Parliament meets, but it will be at my own expense. It would be unreasonable to expect the profession to pay for the printing of an "unauthorised programme." This brings me to the next "reason" or want of "financial support," for Dr. Rentoul's resignation. This was news to me, as I distinctly understood that the fund collected by Dr. Alfred Cox, of Gateshead, early this year, covered Dr. Rentoul's expenses to date. Is this so or not? If so, who authorised Dr. Rentoul to incur a fresh "bill of costs" to the tune of £81 15*s*. which he now demands? Then comes another "reason" which is "second" in the text but "fourth" in order—viz., the hopeless state of the "five Direct Representatives" on the Council. Why should they "fail," and why above all should Dr. Rentoul say it, who boasts what he has done single-handed? They have not failed hitherto. Why should they fail in the future? Fancy a man coming forward to represent the profession whose policy was stamped with the word Failure. Is this "honest"? A man may do his duty and yet "fail" in the sense of securing his immediate object; but what says Lord Lytton of "failure" in one of his charming plays? What said Mr. Disraeli to the Commons who laughed him to scorn in his maiden speech? Lesser lights have striven successfully against enormous odds. The "failure" of Dr. Rentoul to hold his own at the Council table must not be allowed to deter other men from doing their duty and to justify their resignation, nor must his pleading for increased expenditure by the Council be allowed to palliate his offence of forcing the Council to squander hundreds of pounds in an unnecessary election, knowing that this money has to come out of the hard earnings of his fellow practitioners whom he now proposes to further tax with an annual registration fee!

Having dealt with Dr. Rentoul's "reasons" for resignation I have only to add in regard to his "pet schemes" for which more funds are asked that there must be some demand for

[1] THE LANCET, Nov. 20th, 1897, p. 1350.

Digitized by Google

such and proof that they are in the right hands before their author can be permitted to lay a further tax on the profession.—I am, Sirs, your obedient servant,

East Sheen, Nov. 20th, 1897. ALEXANDER McCOOK WEIR.

"THE DISINFECTION OF CLOTHING BY HEAT."

To the Editors of THE LANCET.

SIRS,—Will you kindly give me room for a few lines with regard to the article by Mr. Messiter published in THE LANCET of Nov. 20th, 1897, p. 1305.

Mr. Messiter very properly points out the advantages of current steam and of having some simple and portable form of current steam disinfector for certain public health purposes. Such a disinfector would be specially useful in places where no large disinfecting station exists or where it is desirable to carry out the disinfection of clothes, &c., at the houses of patients affected with infectious illnesses. He appears, however, to be quite unaware of the fact that both these desiderata have been met in Manchester for no inconsiderable time by means identical with those he recommends. He will find in Dr. Niven's report for 1895 full reference to this. It is remarkable that Mr. Messiter should have had constructed an apparatus which corresponds so closely with the one in use in Manchester that even the dimensions of the steam chamber are the same (within a quarter or half an inch). The mode of heating by petroleum furnace was introduced by me in 1894, not only on account of its convenience, cleanness, and cheapness, but also, and more especially, because I could find no other means to obtain rapidly the intense heat required to produce a very rapid ebullition of water, a factor which I consider of very great importance in steam disinfection. Mr. Messiter does not speak in his description of the means he uses for preventing the wetting of clothes by the condensation taking place on the sides of the steam chamber or of the ways in which he prevents the splashing resulting from sharp boiling. The quantity of water he recommends is the same as I have found after many trials to be the best. The method of drying clothes after disinfection is the same which has been taught to the sanitary inspectors in Manchester nearly two years ago.

Coincidences of this kind impress one as indicating the soundness of the method if they come from two absolutely independent sources. In justice, however, to Dr. Niven and myself I think it right to mention the fact that Mr. Messiter recommends methods which we have used in laboratory or public work for at least three years.

I am, Sirs, yours faithfully,

SHERIDAN DELÉPINE,
Professor of Pathology, Owens College,
Nov. 22nd, 1897. Manchester.

To the Editors of THE LANCET.

SIRS,—Professor Delépine having shown me a letter which he is about to send to you in reference to a paper on "A Mode of Disinfecting Personal Clothing at Home," by Mr. A. F. Messiter, M.R.C.S. Eng., which appeared in THE LANCET of Nov. 20th, 1897, p. 1305, I have to confirm his statement that Mr. Messiter's machine, in its shape and dimensions, in the means of heating, and in the purpose for which it is being introduced, is identical with a disinfector invented by Professor Delépine. Professor Delépine's disinfector contains a novel application of physical laws (not to be found in the description of a machine given in Mr. Messiter's article), and its working was demonstrated to the sanitary inspectors of this city over eighteen months ago, by whom it has since been used.

I am, Sirs, yours faithfully,

JAMES NIVEN,
Manchester, Nov. 23rd, 1897. Medical Officer of Health.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Nov. 20th, Mr. Messiter, medical officer of health to the Isle of Axholme District Council, illustrates an apparatus for disinfection of clothes by heat. As I had myself long felt the need of a somewhat similar portable apparatus I exhibited a model of one in the Section of State Medicine, Dublin, in April, 1896, a short description of which you were good enough to give in THE LANCET of May 16th, 1896, p. 1359. I afterwards sent the model to Professor Gairdner, of Glasgow, who forwarded it for exhibit to the medical officer of health of Glasgow. Each medical man in doing battle against the possible conveyance of contagion should be is own detective officer, and should with the most intense energy guard his coming puerperal patient with all the means that lie within his reach against scarlatinal or other poison. Our responsibility in this should make us tremble, as I fear we are indirectly the cause of some deaths. Every man, *paid or unpaid*, ought to be an honest, independent, and courageous sanitary worker.

I am, Sirs, yours faithfully,

Londonderry, Nov. 20th, 1897. WALTER BERNARD.

LOCALISATION AND MEASUREMENT BY X RAYS.

To the Editors of THE LANCET.

SIRS,—With reference to an article on the above subject in THE LANCET of Oct. 16th, of which I was a joint author, and with reference also to other means of localisation which have been suggested before and since, I beg to point out that whether a mechanical or a mathematical method be adopted the necessary apparatus need be only of the very simplest description. The primary requirement is of course a small steady stand to carry the focus tube and allow of horizontal and perpendicular adjustment. This stand may be either of the "Bridge" pattern—i.e., two small perpendicular pillars (with heavy bases) joined by a horizontal bar, the latter capable of being raised and lowered and permitting of lateral displacement of the tube—or it may be the "sliding tube holder" described by Mr. Payne.[1] In any case the horizontal bar must be provided with a knife edge bearing three shallow notches, a central and two lateral ones, the latter equidistant—say, two and a half inches—from this centre. These notches mark respectively a centre and the limit of the lateral displacements of the tube. In the further steps described in the above-named article it is evident that this same stand and these same notches permit of a perpendicular being dropped from the centre one, whilst the two lateral notches now carry the threads which represent the path of the x rays. In other words, the necessity for a second piece of apparatus is avoided—a pair of compasses, a spirit level, and a foot rule complete the equipment. Those who have become accustomed to associate x ray localisation with a formidable arrangement of stands, screws, and spirit levels, reflecting mirrors, cast-iron retouching desks, and yards of millimetre scale, may rest assured that they will lose little in time and nothing in accuracy if at the expense of a few shillings they avail themselves of the simple apparatus I now advocate.

I am, Sirs, yours faithfully,

W. S. HEDLEY, M.D. Edin.
Mansfield-street, Cavendish-square, W., Nov. 23rd, 1897.

"A NOTE ON CYCLING."

To the Editors of THE LANCET.

SIRS,—In the two able and interesting letters that have appeared in THE LANCET of Nov. 13th and 20th the writers make no reference to the two distinct methods of leaning forward: (1) the spine may be bent forward with a stoop of the shoulders; or (2) the pelvis may be rotated and the spine inclined forward without bending and with the shoulders back. Those who have studied river-rowing consider the former method unsightly and injurious while the latter is practised by all skilled oarsmen. To my thinking the same holds true in cycling. The bent back and stooping shoulders are certainly unsightly and the position seems to cramp the chest. On the other hand the body swung forward from the hips, with the back straight and the shoulders back, to my eye is graceful; the position allows freedom to the chest-wall and at the same time the rider gains the mechanical advantage that a forward position certainly gives. There is perhaps more danger of perineal pressure, but this would be avoided if the cycle makers would make a hard saddle with a low peak instead of the very unsatisfactory yielding leather hammock now in use.

I am, Sirs, your obedient servant,

Ottery St. Mary. O. CLAYTON JONES, M.B. Oxon.

"THE PREHENSILE POWER OF THE HANDS OF THE HUMAN INFANT."

To the Editors of THE LANCET.

SIRS,—Mr. Freeman calls attention in THE LANCET of Nov. 20th (p. 1348) to the absence of sexual differentiation in the young human embryo and adds: "The early embryological sexual attributes to which I have drawn attention most probably point to a hermaphroditic ancestry." I fear I cannot agree with him for the simple reason that the embryo even at that stage is far too highly developed for it to be probable that its prototype in the phylogeny was hermaphroditic. It would be as reasonable to suppose because the human infant cannot easily digest anything but milk that therefore it has descended from ancestors who lived exclusively on that diet. This by the way; but the sentence I have quoted betrays on Mr. Freeman's part so far-reaching a belief in evolution that it is difficult to understand why he has recourse to the "special-creation" hypothesis to explain the presence of the prehensile reflex in the infant hand. Granting the truth of the theory of evolution, it affords a sufficient explanation of the fleeting resemblance which the embryo presents in certain particulars to lower forms of life, and to seek additional explanation of that which is already sufficiently explained is suicidal from a logical point of view.

I am, Sirs, faithfully yours,

Southsea, Nov. 21st, 1897. G. ARCHDALL REID.

"A TESTIMONIAL TO DR. JOHN T. ARLIDGE."

To the Editors of THE LANCET.

SIRS,—You will much oblige by inserting in THE LANCET the following further list of subscribers to the testimonial to Dr. J. T. Arlidge.—I am, Sirs, yours faithfully.

THE BUYING POWERS OF TEN POUNDS.

To the Editors of THE LANCET.

SIRS,—I beg leave to bring to your notice some remarks that appeared in the *Willesden Chronicle* apropos of the tendency lately displayed by public bodies to get their medical advice for nothing. The late chairman of the Willesden School Board recently invited medical men to attend at the schools and examine the children gratis, and I regret to say that some men have actually accepted the offer. The board of guardians have recently requested their medical officer in future not to perform any more operations for which they are under contract to pay him according to the Local Government Board schedule, but to send all cases to St. Mary's Hospital as they contribute £10 per annum to that institution, for which sum Mr. Ryan has undertaken to meet the surgical requirements of a parish of close upon 100,000 inhabitants. As most of the guardians are retail traders it is not surprising to find that they are under the impression that they are simply paying the market price of the services rendered at St. Mary's Hospital. In fact, one of them expressed the opinion that they would not be doing their duty to the ratepayers if they paid anything for what they could easily obtain for nothing. I think this is very significant and it is not necessary for me to point the moral. The remedy for this state of things is in the hands of the profession itself. When is it going to wake up and seek its own salvation? I am, Sirs, yours faithfully,

Willesden, Nov. 23rd, 1897. STRUGGLING PRACTITIONER.

*** We print our correspondent's letter but we doubt if his information as to any undertaking on the part of the hospital named is correct.—ED. L

THE EPIDEMIC OF TYPHOID FEVER AT BELFAST.

(FROM OUR SPECIAL COMMISSIONER.)

THE Belfast epidemic presents itself to the observer under two different and distinct aspects. On the one hand there is a sharp, rapidly developed epidemic extending only over a portion of the suburban district of Ligoniel. Then there is on the other hand a more slowly developed, but more persistent, prevalence of typhoid fever in the town of Belfast itself. As opposed to the experience of Ligoniel typhoid fever in Belfast is not restricted to one particular district or to one particular water-supply but exists in all parts of the town. To judge from the facts at present available we seem to be in the presence of a water-borne epidemic occurring side by side with another epidemic which does not appear to be due to the water-supply. Your Belfast correspondent has already described how Dr. Biggar has traced the Ligoniel epidemic to a contaminated spring. This district has recently been added to the city and it was only on Oct. 23rd that the Belfast Water Commissioner obtained jurisdiction over the Ligoniel water-supply. Dr. Biggar is the medical superintendent officer of health of the Belfast board of guardians; and this board of guardians is the rural sanitary authority for the districts lying outside the boundaries of the borough of Belfast. On Oct. 20th, Dr. Biggar was informed that there had been about forty cases of typhoid fever occurring during the previous five days in the upper end of the village of Ligoniel. These persons derived their milk-supply from ten different sources but their water-supply came from one and the same spring. On the other hand the inhabitants of the lower part of the village, though living if anything under worse sanitary conditions, had a different water-supply and they were not suffering from typhoid fever. The whole district has a population of about 5000, but it is only about half of this population that received the incriminated water and there have been more than a hundred cases of typhoid fever among them. How the water was contaminated has already been described. It is not necessary to go over the details again. I may add, however, that the reservoir which is supposed to have been polluted measures some fourteen by six feet and is about six feet deep. The little stream which pases by a cottage where there has been a case of typhoid fever delivers at this point about 600 to 700 gallons of water daily. A great part of this water sank into the field just above the reservoir and disappeared. The subsoil is of limestone. There may be fissures and the water from this brook may have freely mixed with the water of the spring that supplies the reservoir. As the typhoid dejections were thrown out on the garden of the cottage close at hand it is not difficult to see how the contamination may have occurred. In any case, Dr. Lorrain Smith, of Queen's College Pathological Laboratory, has examined this water and reports that he found it was contaminated and he has been able to isolate the typhoid bacillus.

The first measure was to construct a dam across the stream so that the water flowed down the other side of the hill and could no longer reach the field where it was supposed to have mixed with the water of the spring. But this could not be continued as it affected the riparian rights on the stream which had thus been diverted from its usual course. Iron pipes were therefore laid down to convey the water past the field and below the reservoir. This done it was possible to restore the water to its usual channel. At the same time this water-supply was cut off during the space of twenty-four hours. The water that came into the reservoir from the spring was pumped out as fast as it entered, and the reservoir was carefully cleaned out. There is no longer any means by which the water which now comes into this reservoir can mix with the water from the brook, for the brook water flows past in the iron pipes that have just been provided for that purpose. As a result presumably of these measures the epidemic seems to be decreasing.

On the other hand it is not so easy to account for the numerous cases of typhoid fever which have occurred in the town of Belfast. The water-supply is certainly not above suspicion; but it is, in any case, as safe as, indeed safer than, that of London. Dr. Percy F. Frankland, in

Digitized by Google

a report on the subject dated Oct. 13th last says: "By far the greater part of the metropolis is supplied with water drawn from the Rivers Thames and Lea, which drain areas incomparably more densely populated and more highly cultivated than are the gathering grounds of the Belfast supply. In the valleys of the Thames and Lea above the intakes of the London supply typhoid fever is certainly at all times present among the population." Yet the typhoid fever mortality in London for the ten years from 1881 to 1890 only averaged 1·9 per 10,000 of the population, and this is much below the average of ten out of fourteen large English towns which are reputed to have water-supplies above suspicion. Dr. Frankland then adds the following argument: "If London, which is supplied with water initially far more exposed to contamination than is that of Belfast, exhibits no excess of typhoid fever mortality but, on the contrary, a very low average death-rate from this disease it is difficult to see why the water of Belfast, which is submitted to the same treatment of storage and filtration as is that supplied to London, should be credited with the communication of this disease, more especially as the Belfast water is subjected to a far more prolonged storage than is the case with any of the water supplied to London. It is particularly noteworthy, in connexion with water-borne epidemics of typhoid, that these have in almost all cases occurred through contamination of water, which was supplied generally without storage and almost invariably without filtration." Dr. Frankland, in support of this contention quotes the evidence he gave before the Royal Commission on the London water-supply (1892) concerning the West Middlesex Waterworks. He then showed that unfiltered Thames water from Hampton contained 1437 bacteria in a cubic centimetre. After passing through one storage reservoir this same water contained only 318 bacteria, and after a second storage 177 bacteria per cubic centimetre. In a previous report on the water-supply of Belfast, dated July 24th last, Dr. Frankland says: "With storage capacity the Belfast supply appears to be well provided, both the Woodburn and Stoneyford waters being subjected to a protracted period of quiescence in the large reservoirs bearing these names. A slight defect in this storage system I have already referred to—viz, the admixture of some unstored water with the stream below the Woodburn reservoirs. The benefits of storage are also to some extent neutralised in this portion of the supply by passing the water from these reservoirs through an open stream clothed with vegetation instead of exclusively through a closed culvert. The Belfast water-supply is further provided with a most admirable series of filter beds constructed on the most approved principles and worked with great care and attention.' This latter includes the allowing of a considerable amount of water to run to waste whenever a filter bed has been cleaned, so that there may be time for the slime deposit to form itself on the surface of the sand before the water is distributed for drinking purposes. The result of these measures was that in the worst sample 96 6 per cent. of the bacteria in the unfiltered water had been removed, and in the best sample 98 8 per cent. had been removed. In spite of these good results it is at least theoretically possible that the water might be contaminated, but Dr. Frankland concludes in his last report that "it appears in the highest degree improbable that the typhoid now prevalent in Belfast should be chargeable to the water as sent out to the consumer." To this he adds that as there are two water areas it is not likely that both would be simultaneously contaminated; and, if one only was contaminated, then the fever, instead of being spread all over the town, would be limited to the district provided by that supply.

In spite of these reassuring utterances, a strong impression prevails that the water is the cause of the epidemic. It is argued that Dr. Frankland was not fully informed as to all the circumstances. Thus it is a mistake to say that there are two separate water-supplies. The gathering grounds are quite separate, but the waters meet together and are mixed at the filter beds. Consequently Dr. Frankland has been called to Belfast for a third time and a list of sixteen farm houses has been given to him where the drainage from the stables, manure heaps, houses, &c., discharges either into the subsoil or the adjoining small water courses which are all situated on the Stoneyford gathering ground supplying Belfast with drinking water. At the commencement of the year there were four cases of typhoid fever in one of these farm houses, and it is urged that it was only after these four cases on the gathering ground that the fever became so general in Belfast. But here we are face to face with a difficulty. The cases at this farm, if I am rightly informed, occurred last January and the compulsory notification of infectious diseases only came into force last March. In the month of January 33 cases of typhoid fever were voluntarily notified and in February 14 cases. Now in the month of March when compulsory notification came into force 215 cases of typhoid fever were reported. The figures for the following months were as follows: April, 239; May, 527; June, 262; July, 172; August, 304; September, 379; and October, 354. Thus from January to the end of October we have a total of over 2000 cases notified as typhoid fever. There is every reason to believe that some errors in diagnosis have been committed. This is shown by the fact that a good number of the patients were up and well and attending to their business two or three days after they had been reported to the medical officer of health as suffering from typhoid fever. What, however, is still more significant is the fact that the number of deaths registered as due to typhoid fever do not at all correspond with the number of cases said to have occurred. There were 12 deaths in January, 19 in February, 16 in March, 35 in April, 40 in May, 35 in June, 9 in July, 30 in August, 27 in September, and 33 in October. Since then 9 deaths were reported for the week ending Nov. 6th, and 5 deaths for the week ending Nov. 13th. This gives us for the year and up to Nov. 13th 270 deaths from typhoid fever. But typhoid fever is endemic at Belfast, there having been 145 deaths from that disease in 1894, 184 in 1895, and 136 in 1896. Thus we may say that typhoid fever is much more prevalent this year than usual; but the difference is not so startling as to justify the belief in the presence of some very exceptional cause. If the water had been unusually contaminated we might have expected a greater number of deaths and a more uniform distribution of the disease. Though there are cases in all directions still the great majority are confined to two districts widely apart—namely, the high-level Shankhill and Crumlin district, and the low-level district on the other side of the water known as the Ballymagarret and the Newtownwards-road district. Then in the first, the Shankhill district, there are the barracks, the prison, and the union workhouse, with some thousands of inhabitants drinking the same water and yet escaping from the fever.

What, then, are the causes of the present prevalence of typhoid fever at Belfast? This is a complex question with which I cannot venture to deal till I have carried my investigations farther afield. But I may at least say this much, that not only is the soil unfavourable, alluvial and moist, but it is highly contaminated by some 20,000 cesspits that still exist in the town. Many of the houses cannot be approached from behind so that the contents of the cesspits have to be carried through the kitchens and the inhabited parts of the houses. A vast section of the population is singularly careless as to sanitary matters. Proper precautions are rarely enforced and there is little or no skilled nursing. The climate also is very damp and the flax spinning in which a large section of the population is occupied is unhealthy work. But all these are matters which I must discuss more fully when I have had the time to collect more evidence. For the present I must content myself with saying that I have not yet come across sufficient proof to be able to conclude that the present exceptional prevalence of typhoid fever in Belfast is due to a general contamination of the water-supply; but that there is much to show that the condition of the subsoil, the want of proper drainage, and the habits of the people are all well calculated to facilitate the spread of such a disease as typhoid fever.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Drainage Prosecution.

AN important prosecution under the city by-laws as affecting drainage was heard at the Police-court recently. A builder submitted plans for the erection of a number of houses which were disapproved by the corporation owing to certain defects. Again and yet again the plans were rejected. The houses were put up without the proposed alterations, hence the action by the corporation. It was stated that there was one inlet and one outlet for each house instead of two,

Digitized by Google

and only one trap for the six houses. In accordance with the by-laws each house should have a separate connexion with the main drain. For the defence it was alleged that previously to the appointment of the present city surveyor the corporation allowed blocks of houses to be drained with one trap. An expert stated that in his judgment there was no sanitary defect in the plan followed and that a different interpretation was placed upon the by-laws to that previously existing. The Bench held that the by-laws had been broken and fined the defendant 20*s.* and costs, granting a case for appeal. Besides the question of legal interpretation of the by-laws the construction of the drainage from a sanitary point of view is important. Authorities appear to differ upon this arrangement, some considering that the system of interception traps are an unnecessary evil. An authoritative solution of this difficulty would go far to dispel the apprehension which exists as to the best plan of drainage for dwelling-houses, more especially in the face of prevalent enteric fever cases.

The Police and Assaults.

The repeated advice given by magistrates to the police as to the use of the staff in self-defence is prudent and judicious. They are recommended not to be aggressive, and when force is necessary to take care that they shall not strike the heads of their assailants with truncheons. This is no doubt wise as a sentiment of calm and reflective consideration from the bench. In the excitement of a street row under extreme provocation and often personal injury human nature is apt to assert itself and blow to be returned for blow. A police officer was lately convicted of viciously assaulting four men in a crowd and was sentenced to one month's imprisonment. The officer had been previously knocked down twice and kicked, when he got up in a sort of dazed way and ran amok among the crowd of bystanders. Some efforts have been made to obtain an appeal on the ground that an injury to the head such as the constable received frequently causes irresponsibility of immediate action. While recognising the danger of this plea in many instances it would appear probable from subsequent evidence that this might be reasonably allowed in this particular case, and I am glad to say that an appeal has ultimately been admitted, the necessary recognisances being entered into. Justice demands that the circumstances should be fairly and fully investigated on behalf of the police as well as for the protection of the public.

The Catacombs of Christ Church.

Under the recent Birmingham Churches Act the building of Christ Church is to be removed and the site sold. Under the church are catacombs containing 137 bodies, very few of which have been claimed by their descendants. The celebrated Baskerville is buried here. Failing sufficient interest with the surviving relatives these bodies will be removed to Wilton Cemetery for interment, that of Baskerville being reserved for St. Philip's Churchyard in the centre of the town of his labours.

Nov. 23rd.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Guardians and Chemical Odours.

PROBABLY in Oliver Twist's time nothing would have been done to protect him from bad smells but it must be acknowledged that no smells then existed which could be compared for sickening persistency with those now provided abundantly by the ingenuity and liberality of some of our chemical manufacturers. So shockingly offensive are these smells that the Prestwich guardians have asked the Manchester guardians to join them in a deputation to the sanitary committee of the Manchester Corporation "to direct attention to the nuisance which was caused by the smells from certain chemical works." It is no wonder that the two boards should act together in this matter, as the Prestwich and Crumpsall workhouses are near neighbours. As regards nuisances chemical manufacturers seem to be especially prominent. They are among the most diligent in the production of black smoke, and so highly do they value their proficiency in this art that they seek for greater privileges than are allowed to other manufacturers, while they are unrivalled in the skill with which they concoct bad smells and distribute them to the unfortunates who dwell around. No doubt something has been done in various places to put partial restraint on them, but there are well-known instances in Manchester where all such efforts have been evaded or defied. The practical applications of chemical science must be defective when the result is an almost unendurable nuisance, and it is time that the offenders should be compelled to have more regard for the comfort and well-being of others than they now exhibit, and they might as a change apply their science to the prevention instead of the production of bad smells.

Manchester Children's Hospital.

On Nov. 13th many of those interested in the Manchester Children's Hospital assembled at St. Anne's-on-the-Sea to take part in the formal opening and presentation of a convalescent home by Sir Wm. Agnew, president of the hospital. By his munificence in building and also in the equipment of this home a need long felt has been relieved. It is amply provided with ground for extension and stands some sixty or eighty yards from the coast line. There is accommodation for twenty-five boys and girls as well as for a matron, two nurses, and two servants. The Rev. S. A. Steinthal said that Sir William Agnew had that morning given £500 towards the endowment and that £350 or £400 a year would be required for the maintenance of the home. This will no doubt be found, for the hospital has many friends.

The Coachman with Medical Instincts.

The medical profession is familiar with many varieties of irregular competition, but it is comparatively rare that the medical man's coachman turns practitioner. That such a thing does happen sometimes is shown by the evidence given at an inquest held by the Manchester city coroner on the 17th inst. as to the death of a child three days old. At the birth a nurse and the uncle of the child's father—"who was considered very clever at the game"—were present. It was given in evidence, according to the newspaper report, that he was acting as assistant to a medical man, and when Mr. Smelt, the coroner, told him he had a distinct recollection that he was the late Mr. Pettinger's coachman the man acknowledged that it was so. It is a little hard on Dr. Nichol, a well-known practitioner in the neighbourhood, that he should be opposed by Mr. Nicholls—sometime coachman, now accoucheur — however clever he may be "at the game," and it seems to be a case which deserves inquiry by the Manchester Medico-Ethical Association. The coroner observed that "a person who knowingly engaged an unqualified man had to be content with the outcome," but the profession generally should not be content when such scandals are possible. The medical man does not seem to have been present at the inquest.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Social and Sanitary Society of Edinburgh.

THE annual meeting of this society was held in Edinburgh on Monday. After the report for the past year had been read and adopted Dr. Brock, the medical officer of health of Midlothian, spoke at some length on the milk question. He emphasised the necessity of a pure milk-supply and pointed out the liability to infection with tuberculosis and other infectious diseases through the milk-supply. Tuberculosis was responsible for one-seventh the total deaths in that country and dairy cows were tuberculous to the extent of from 20 to 50 per cent., so that it was necessary to make every effort to eliminate this source of infection. The disease might be communicated by cream, butter, cheese, and buttermilk, as well as by milk. To ensure a non-tuberculous milk-supply it was necessary that the animals should be systematically tested with tuberculin and that all the tuberculous cows thus discovered should be weeded out of the herds. To guard against infection with scarlet fever he thought various precautions necessary. The dairy buildings should be removed from the neighbourhood of dwelling houses, the milk should go straight from producer to consumer, and the people employed about a dairy should be regularly inspected by a medical man. He advocated the formation of a dairy company with the view of providing a pure milk-supply. He showed how much good

Digitized by Google

could be done by workers of the society if as well as distributing leaflets they would enter the houses of the poorer classes and demonstrate to them how to render milk innocuous by sterilisation. Dr. Brock then moved a resolution that the society pledges itself to use all means in its power to further the necessary reforms in connexion with the milk-supply. The resolution was adopted.

Edinburgh Royal Infirmary.

At the meeting of the managers of the Royal Infirmary held this week the treasurer and clerk submitted a report on the income for the financial year. The ordinary income from all sources amounted to £30,620 2*s.* 11*d.*, being a decrease of £62 14*s.* 8*d.* as compared with last year. The extraordinary income showed the large increase of £4390.

Edinburgh Royal Physical Society.

At the first meeting of this society held last week Professor J. Struthers delivered an address on Rudimentary Structures and their meaning in Man and in Certain Animals. In the course of the address he said that one occasionally meets among those who have studied human anatomy only with persons who believe in the utility of every structure and in the independent origin of every species. He therefore would mention a few easily understood examples of structures occurring in man and animals no longer useful, but merely vestigial remnants, modifications of previously existing structures. He specified as belonging to this category the vestigial hind limb in the whale, the teeth of the young whale, and the vestiges of lateral toes in the horse. He spoke also of the vermiform appendix and of Meckel's diverticulum in this relation and concluded with a quotation from Darwin.

The Western Infirmary Dispute at Glasgow.

No public announcement as to the exact position of this controversy has yet been made, but it is known that negotiations between the managers and the University authorities are at present in progress and it is reasonable to hope and even to expect that a satisfactory issue will be the result. The annual meeting of the subscribers to the infirmary has to be held during the present week and the managers will in the report they submit to that meeting be almost compelled to define and defend their policy. The absence of any official statement has not, however, prevented certain echoes of the controversy from reaching the public ear. Thus Professor Gairdner has written to the press in reference to the statement prepared by Dr. J. B. Russell for the Faculty of Physicians and Surgeons. Professor Gairdner endeavours to negative Dr. Russell's contention that the University has attempted to encroach upon the clinical facilities and teaching offered by the infirmary. He does not, however, meet the specific instances quoted by Dr. Russell in support of his position but contents himself rather with a general negative to Dr. Russell's affirmation. No one for a moment believes that Professor Gairdner personally desires any unfair advantage or doubts his generous recognition of the work and ability of the non-collegiate clinical teachers, but whether the corporate influence of the university has been applied in this spirit is fairly open to question. That as the infirmary has been enlarged some physicians and surgeons have been appointed to the visiting staff who are not University professors without serious opposition from the University is surely no proof of the generosity of the latter body seeing that their four professors of medicine and surgery were already provided with wards, and some of the elections just referred to were not quite free from opposition from University quarters. Professor Macewen's position is being strongly supported by the *Glasgow Herald* and the controversy is being used with a view to raise certain aspects of the question of infirmary management. In none of the Glasgow infirmaries is there any representation of the staff on the board, and in each, too, the superintendent is a medical man. It is now being contended that in both of these respects the management ought to be altered and from certain movements which are in progress there is reason to believe that an organised agitation in support of this view is to be instituted. The only other incident in connexion with the controversy that falls to be noted is the publication of a letter signed by the majority of the visiting staff expressing appreciation of the manner in which they have always been treated by the managers and the superintendent. Professor Macewen's name is not appended to this document, nor is he the only absentee, and probably the names of those who have abstained have attracted more attention than the actual signatures.

Glasgow University.

At the September meeting of the University Court a letter was read from the Universities' Commission in answer to a memorandum from the court dealing with the proposal to confer disciplinary or penal powers on the University so far as its graduates are concerned. The effect of the letter was that the Commissioners declined to deal with the matter, regarding it as outside the scope of their powers. The court made the following appointments: Mr. L. R. Sutherland, M.B., C.M. Glasg., lecturer on pathology for the present academic year during the absence of Professor Coats; Mr. G. Burnside Buchanan, B.A. Cantab., M.B. Glasg., to be assistant to the professor of clinical medicine, vice J. C. Renton, M.D. Edin., resigned; and Professor Young and Professor Barr to be governors of the West of Scotland Technical College. Mr. R. Barclay Ness, M.A., M.B. Glasg., has been appointed an assistant to the professor of medicine.

Nov. 24th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Royal College of Surgeons in Ireland.

THE examination for the Fellowship of this College has recently concluded, when six candidates were adjudged to have passed the primary portion and one the second and final part. The recent regulation by which students who have passed the second professional examination of the College or the half M.B. examination of the Dublin University are entitled to present themselves for the primary examination for Fellowship was taken advantage of by three candidates who had fulfilled the necessary conditions—namely, two students of the medical school of the College and one of the Dublin University.

Typhoid Fever in Dublin.

Although the general death-rate of Dublin has recently been more than usually satisfactory the deaths due to zymotic diseases have been above the average. What may be called an epidemic of typhoid fever now prevails at the north side of the city. A large number of cases have been admitted to the Mater Misericordiæ Hospital, while many of the trained nurses from that institution are employed in the treatment of patients suffering from typhoid fever in the immediate neighbourhood. The disease seems to have first appeared in the recently-built Mountjoy station of the Metropolitan police, where no less than seven men out of the twenty-four in the force there were attacked. It was first surmised that the soil on which the new building rests might have been infected by sewage. Sir Charles Cameron has, however, been actively investigating the matter and seems to have traced the outbreak to an institution which supplied milk to the police-station and in which there have been a number of cases of enteric fever which were never notified, the Act for the Notification of Infectious Diseases not being in force in the district. It has now been ascertained that ninety cases of typhoid fever have recently occurred in this particular suburban district not far removed from the city boundary. At the last meeting of the guardians of the Drumcondra township a letter was read from the medical officer of health, Mr. Nedley, referring to the prevalence of fever at the north side of the city, and stating that after visiting and examining at the request of the board a certain house which was said to be in an insanitary condition he had come to the conclusion that the infection must have been conveyed from outside their area which was healthy at present.

The Apothecaries' Hall of Ireland.

The list of examiners in medicine, surgery, and midwifery, appointed by the Governor and Court of the Apothecaries' Hall of Ireland has just appeared. The names should be a guarantee that the examination for this old-established license will for the future be properly conducted.

The late Dr. James Cagney.

Dr. Cagney had many friends in Dublin who were shocked and grieved by the news of his untimely death. The Irish Medical Schools' and Graduates' Association in London will find it very difficult to adequately fill his place.

The Typhoid Fever Epidemic at Ligoniel.

There have been eight fresh cases notified and three deaths since my last report. At a meeting of the board of guardians held on Nov. 16th a member of the board of guardians stated that he had visited the district of Ligoniel and had found a very serious state of affairs. In Lower Ballysillan some 300 people were supplied with water which passed through an open tank from which cattle were allowed to drink. He had also found that there were some ninety-seven houses in the upper end of Ligoniel with only two dry closets for all the inhabitants. He characterised it as a most scandalous state of affairs. The Water Commissioners are at present laying a 6-in. main, and in the course of about two weeks it is hoped that the objectionable tank will be removed. It was decided to refer the question of the houses which are without closets to Dr. Bigger and Mr. Milligan. Ligoniel is certainly in a most insanitary condition.

Prosecution in Belfast under the Public Health Act.

On Nov. 16th a woman was fined in Belfast for allowing her niece to go to school while suffering from typhoid fever. The child was sent to attend an examination. The case was brought forward for the purpose of letting the public know that such an offence could not be tolerated.

The Mater Infirmorum Hospital, Belfast

On Nov. 22nd the Right Honourable the Lord Mayor of Belfast opened a bazaar in the Ulster Hall, the object of which was to aid the executive committee of the Mater Infirmorum Hospital in providing a large balance of the total estimated probable outlay of £50,000 required to complete the buildings and equip this new hospital. The Roman Catholic Bishop presided and there was a very large attendance of the friends and supporters of the charity, and it is hoped that a large sum of money will be realised. The new Mater Infirmorum Hospital is now nearly completed and will be a most desirable addition to the charitable institutions of the city. Situated on the Crumlin-road with a frontage of 230 feet it occupies an area of slightly over one acre. The hospital which is built on the "pavilion" system has a centre administration building, with two lateral blocks for the patients. It is planned for 137 beds and 8 cots for children. The buildings are of red brickwork with stone dressings, the compartments are heated by steam and lighted by electricity, and everything that modern science and the latest experience could suggest has been done to make the hospital complete in every respect. A novel feature is the introduction of garden roofs for the use of convalescent patients. They cover the great pavilions and are well protected and sheltered. It is expected that the new Mater Infirmorum Hospital will be open for patients early in the new year.

The Belfast Royal Hospital.

At the quarterly meeting of this hospital held on Nov. 22nd Dr. Lowry, Dr. Mateer, and Mr. Montgomery were elected senior and junior house surgeons and house physician respectively.

Death of Dr. O'Connor, of Ballycastle.

Extreme regret is felt amongst his wide circle of friends in the medical profession and amongst the public at the death at a very advanced age of Dr. G. Matthew O'Connor, of Ballycastle. Educated in Dublin where he graduated M.B. of Trinity College in 1842, Dr. O'Connor spent the greater part of his life in Ballycastle, where he was medical officer of the workhouse and where he enjoyed an unusually large practice. Dr. O'Connor was a man of the most refined nature and of the most kind and gentlemanly character. His long experience and training made his opinion a most valuable one, and it is given to few medical men to be so thoroughly respected by their patients as Dr. O'Connor was. His death leaves a great blank in the roll of the older members of the medical profession in Ulster, and of no man can it be said with more perfect truth than of Dr. O'Connor that he earned the respect, the esteem, and the confidence of every one with whom he was brought into contact.

Nov. 23rd.

ON Monday, Nov. 22nd, the Cambridge Graduates' Club of St. Bartholomew's Hospital held their annual dinner at Frascati's Restaurant. The Vice-Chancellor of Cambridge University, Dr. Alexander Hill, was in the chair. Seventy-five members and guests sat down to dinner and the evening was in every way a great success.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Opening of the Annus Medicus.

THE University of Rome was opened for the winter by Professor Giovanni Battista Grassi who holds the chair of comparative anatomy and whose high reputation, enhanced by the English Royal Society having awarded him the Darwin medal for the best recent vindication of the law of evolution, attracted a numerous and distinguished audience. His discourse which occupied more than a hour had for its subject, "Critica della Filosofia Zoologica" and in a series of rapid but luminously effective side-glances went round the whole circle of the biological sciences. In none of these, he said, can the student afford to be a specialist, zoology itself having relations more or less intimate with all, which in turn are in varying degrees its debtors. In illustration of this last assertion he showed what physiology and biology have of late years owed to zoology, particularly in the "diramazioni" (ramifications) of the embryonal cell and he took occasion to eulogise the discoveries in this field by the Italian Camillo Golgi and the Spaniard Ramon Casali. A masterly survey of "bio-mechanics" (the mechanism of development), a science yet in its infancy, led up to the doctrine of man's rise and progress. As a theory—nay, as a law—evolution is inexpugnable, but it cannot solve the mystery of animal origin. As to its own vindication it must appeal to something more conclusive than "the struggle for existence." Darwinism and Neo-Darwinism are at best provisional bulwarks of the theory requiring still the "sussidii della zoologia" (the reinforcements of zoology) to enhance their sufficiency. From this stage Professor Grassi proceeded to illustrate the "exclusively critical character of zoological method" and made typical applications of it to anthropology and psychology, showing that what in the lower animals are "instincts" become specialised in men into "powerful impulses directed to the good, the beautiful, and the true." Thus far the zoologist can go without running the risk of trenching on the domain of metaphysics. Nature-study (physics in its largest sense) must be disjoined from metaphysics, and should the "fisico" (nature-student) arrive at intuitions which tend to enlighten the "metafisico" it is his duty "to express himself with caution." In the business of life and in applied psychology the zoologist remains an inadequate guide. In illustration of this position Professor Grassi ably examined the relations between zoological method and religion, anarchy, and socialism. The study of the instincts constrained to the belief that from society as now constituted religion cannot be excluded, while in their own interests Catholics have come to admit that it is not heretical to suppose that the human body is derived from some antecedent animal. They have ceased to declare war against the law of evolution. A rapid incursion into the troubled waters of "criminal anthropology" brought the lecturer alongside Lombroso and his school, with whom he declared himself in sympathy provided they made their science really sound and socially useful, "ricorrendo al positivismo dell' analisi zoologica." Similar was his attitude towards modern socialism while making large deductions from its premature ideals. "Given the progress of every created being, man tends to the integration of intelligence, to the knowledge of things in their essence. Herbert Spencer, judging ours to be a period of 'ecoessivo perfezionamento,' foresees the break-up of existing society from the débris of which will germinate the new era. But faith in our ideals," contended the orator, "will have power to save us from this decadence and from all such moral eclipse." The above is the merest outline of a discourse which, highly condensed and fraught with "pregnant epigram," was yet listened to with profound attention till its close when a loud and long outburst of applause gave vent to the feelings of the audience. In its published form it will doubtless provoke criticism and stir up controversy, but as to its ability and grasp of scientific results and tendencies there will be but one opinion. The University of Rome, I may add incidentally, was more numerously frequented last year than in any preceding one. This year, too, it makes an excellent start with 927 law students, 854 medical, 306 in physics and mathematics, 250 in literature and philosophy; 2337 in all.

The Serum against Yellow Fever.

Professor Sanarelli (a correspondent tells me) delivered on the 14th ult. in Montevideo a lecture before an audience of medical practitioners and students on "Immunità contro la Febbre Gialla," in the course of which he showed that the serum of the blood of the human subject dead from yellow fever if injected into animals manifests no preventive power against the bacillus icteroides, while the serum of the blood of convalescents from the fever possesses a mild preventive action. Although, he continued, the simultaneous injection of the serum of convalescents and of the virus did not save from death yet a fatal issue was avoided in most cases when the injection of the serum was made, twenty-four hours before that of the virus in the dose of at least "due centimetri cubi." Professor Sanarelli added that the human serum obtained from sundry individuals in normal condition and convalescent from other maladies, although administered in high doses, never produces in animals the slightest preventive or curative action. Wishing to immunise animals against experimental yellow fever he had to abandon rabbits and after them goats and lambs on account of their excessive sensibility even with minimum injections of the virus. His experiments accordingly were restricted to guinea-pigs, dogs, and horses. He began by injecting the icteroid toxin in the dose of 0·01 c.c. The crisis of the first injection being over—a crisis lasting from twenty to thirty days—injections were made of 0·05 c.c. of toxin, and continuing at this rate he succeeded, only after six or seven months, in obtaining one guinea-pig well "vaccinated" against the bacillus icteroides. The dog and the horse respond much better to injections of the virus than the guinea-pig. At present Professor Sanarelli has in his laboratory three dogs and two horses well "vaccinated" which have yielded serums giving perfect immunisation against the experimental yellow fever in animals. On the strength of these experimental facts Professor Sanarelli says that in all likelihood—not to say certainty—this very serum which saves animals destined to succumb almost without exception to experimental yellow fever might be useful in the treatment of spontaneous yellow fever occurring in man, while possessing, moreover, a distinct preventive action against the disease.

Nov. 20th.

Obituary.

JAMES CAGNEY, M.D. R.U.I., M.R.C.P. LOND.

IT was with great regret that we announced last week the death of Dr. James Cagney at the early age of thirty-eight. Dr. Cagney carried out as usual the arrangements in connexion with the dinner of the Irish Medical Schools' and Graduates' Association which took place so recently as Nov. 2nd, but it was then noticed by several of his acquaintances that he was very unwell. He promised that he would take rest and advice on the following day, as a temperature of 102° F. suggested that he was suffering from influenza; the sequel showed, however, that while he had been trying to shake off a vague malaise by cycling and golfing, he was really entering the second week of an attack of typhoid fever which, as our readers already know, proved to be fatal.

James Cagney was born at Cork in 1859, his father being a well-known merchant in that city whilst on his mother's side he was descended from military medical officers through several generations. Coming of a Roman Catholic family he was educated at Ushaw, whence he passed with a high place in honours the London Matriculation Examination at the age of sixteen years. At Queen's College, Cork, where he went on leaving school, he distinguished himself in classics at the intermediate examination in arts and headed the list of candidates in mental and moral science at the M.A. degree. Having taken degrees of M.D., M.Ch., and M.A.O. in 1883 he made two voyages as a ship's surgeon, one to Australia and another to the Pacific. After these—that is, in 1885—he came to London for a course of post-graduate work at St. Mary's and St. Thomas's Hospitals. At the former he studied neurology in particular, and when Dr. De Watteville resigned his appointment as medical officer in charge of the Electro-therapeutic department of the hospital in 1890 Cagney succeeded him. From 1886 to 1894 he was also one of the demonstrators of anatomy at the St. Mary's Hospital Medical School. In 1889 he was elected physician to the Regent's Park Hospital for Epilepsy and Paralysis and in 1893 he was appointed assistant physician to the North-West London Hospital. At the time of his fatal illness he was in attendance at all three hospitals and his triple duties occupied no less than five afternoons in each week. He carried the same enthusiasm into other ramifications of his professional career. He was a regular attendant at the medical societies and two years ago he was secretary to three simultaneously, viz.: the North-West London Clinical Society, the Harveian Society of London, and the Irish Medical Schools' and Graduates' Association. What he did for the latter as its metropolitan secretary by his tact and energy is well known to all Irish medical men practising in England. Some years since one subject loomed largely on the Association's programme—namely, the ineligibility of Fellows of the Irish colleges to positions on the staffs of English hospitals. Dr. Cagney's exertions to obtain better treatment for his countrymen can be appreciated only by those who were actively associated with him in the work. He was himself a member of the Royal College of Physicians of London and was moreover connected with a metropolitan teaching hospital where there are no restrictions with regard to the source of the qualifications of the members of the staff, so that there was no question of his fighting for his own hand.

Dr. Cagney was a frequent speaker, mostly on neurological subjects, at meetings of the medical societies, and his words were always interesting and well chosen. His best piece of experimental research was in reference to the effect of suspension on the vertebral column, carried out in the dissecting room and post-mortem room at St. Mary's Hospital. This was inspired by the suspension treatment of locomotor ataxia so much in vogue about the years 1889 and 1890. In two papers, one read before the Royal Medical and Chirurgical Society and the other before the Anatomical Society and published in the Journals of those societies for 1890, Cagney clearly showed by a number of ingenious dissections and experiments that the effect of swinging and hanging postures on the vertebral column was to relax, not to stretch, the spinal cord. He contributed various papers to our own columns and those of other medical journals on Peripheral Neuritis, and at the time of his death he was engaged in collecting material for a small book on this subject. The three editions of "Clinical Diagnosis" which he translated and edited from the German of von Jaksch took Dr. Cagney into an altogether different field of medical thought, and the appreciative reviews which have from time to time appeared in this and other journals have testified to the skill with which he translated that work and to the judgment he showed in the incorporation of only the best English methods of research which were not contained in the original German edition.

James Cagney impressed all who came in contact with him as being a man of culture and high intellectual capacity. Those who knew him marvelled how, in spite of his many professional ties, he managed to find time for the discharge of the duties of an active volunteer—he was Surgeon-Captain of the "Artists,"—for golf, cycling, shooting, and numerous social engagements. But he appeared to lead his full life with ease and to make friends wherever his handsome presence and distinguished manner were to be met with.

A large circle of personal acquaintances (some 300 in number) attended the requiem mass which was offered St. James's, Spanish-place, on Monday, Nov. 22nd. Among those present were Lady Matthews, Judge Bacon, Sir William Broadbent, Dr. W. J. Collins, Dr. Frederick Roberts, Dr. Sydney Phillips, Mr. P. J. Freyer, Mr. W. H. Battle, and Dr. G. William Hill.

CUTHBERT WYMAN, M.D. CANTAB., F.R.C.S. ENG.

DR. CUTHBERT WYMAN, of Putney, who died on Nov. 21st as the result of an attack of pneumonia, was a distinguished student of St. Thomas's Hospital, where he gained the Solly Medal and held several resident appointments. He graduated as M.A. and M.B. at Cambridge University in 1891 and as M.D. in 1895; he became a Fellow of the Royal College of Surgeons of England in 1892. He recently gave a lecture on

Digitized by Google

India before a large audience in Putney, the proceeds, amounting to about £50, being handed to the Indian Famine Fund. Baron Pollock, who died on the same day as Dr. Cuthbert Wyman, was in the chair at the delivery of this lecture. Dr. Cuthbert Wyman was very popular in the district and will be much missed.

ALEXANDER MONRO INGLIS, M.D. EDIN.

DR. INGLIS, of Montpellier Lawn, Cheltenham, died in London on Nov. 20th. He studied medicine in Edinburgh, graduating as M.D. in the university there in 1854, and many years ago settled in Cheltenham where he became physician to the General Hospital and eventually had an extensive practice. On resigning his hospital appointment, being then the senior physician, he was elected consulting physician. Dr. Inglis became a Licentiate of the Royal College of Surgeons of Edinburgh in 1854, and a Member of the Royal College of Surgeons of England in 1858. His death is deeply regretted by his numerous friends.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. A. Sheffer, Professor of Medical Chemistry in the University of Kieff.—Dr. Poisson, Professor of External Pathology in the Poictiers Medical School.—Dr. Chenantais, formerly Professor of Clinical Surgery in the Nantes Medical School.—Dr. Jacquemet, Professor *agrégé* in the Montpellier Faculty of Medicine.—Dr. Cristino Cebrian, Professor of Anatomy in the University of Salamanca.—Dr. Jazenko, Emeritus Professor of Surgery in the University of Kieff.—Dr. A. Bykow, formerly Principal of the Warsaw Medico-Chirurgical Academy.

SOUTH-WEST LONDON MEDICAL SOCIETY.—The second meeting of the current session was held at the Town Hall, Wandsworth, on Nov. 10th, the President, Mr. T. A. I. Howell, being in the chair. Mr. P. J. Freyer read an interesting paper on the Modern Methods of Diagnosis of Stone in the Bladder, giving a *résumé* of 900 cases and showing the instruments employed in the treatment of these diseases. A cordial vote of thanks was awarded to the lecturer at the close of the meeting.

FOREIGN UNIVERSITY INTELLIGENCE.—*Albany (Medical College):* Dr. Geo. Blumer has been appointed Assistant Professor of Histology, Pathology, and Bacteriology.—*Baltimore (Medical College):* Dr. Wm. E. Moseley has been appointed Professor of Gynæcology in succession to Dr. Ashby.—*Berlin:* Dr. Richard Greef has been appointed to the charge of the Ophthalmic Department in the Charité Hospital vacant by the death of Professor Burchardt.—*Greifswald:* Dr. Egon Hoffmann, *privat-docent*, has been promoted to an Extraordinary Professorship of Otology.—*Groningen:* Dr. Heyenga has been appointed Professor of Midwifery and Gynæcology in succession to Dr. Dödeshein who goes to Tübingen.—*Heidelberg:* Dr. Walter Petersen has qualified as *privat-docent* in Surgery.—*Königsberg:* Dr. Jaeger has qualified as *privat-docent* in Hygiene.—*Missouri:* Dr. W. Ophüls, Second Assistant in the Göttingen Pathological Institute, has been offered the chair of Pathological Anatomy and Bacteriology.—*Munich:* Dr. O. Krummacher has qualified as *privat-docent* in Physiology.—*Rostock:* The names selected for the Ophthalmic Chair vacant by the death of Professor Berlin are—(1) Dr. Axenfeld, of Breslau; and (2) Dr. Greef, of Berlin.—*St. Petersburg (Military Medico-Chirurgical Academy):* Dr. V. Grusden has been recognised as *privat-docent* in Midwifery.—*Tübingen:* Dr. Eugen Wintenitz, *privat-docent* of Midwifery and Gynæcology, has been promoted to the rank of Extraordinary Professor.—*Turin:* Dr. Scipione Vinaj, of Modena, has been recognised as *privat-docent* of Hydrology.—*Vienna:* Dr. Alois Kreidl, Dr. Hans Rabl, and Dr. Karl Ullmann have been recognised as *privat-docenten* respectively of Physiology, Histology, and Dermatology with Syphilography. Dr. Siegmund Fuchs has been appointed Extraordinary Professor of Physiology. Dr. J. Bille has been appointed to take charge of the Dermatological Department of the Policlinic.—*Warsaw:* Dr. Edward Przewoski has been appointed Extraordinary Professor of Pathological Anatomy.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

TUESDAY, NOV. 23RD.

THE sixty-third session of the General Council of Medical Education and Registration was opened to-day in the offices of the Council, Oxford-street, London. Not only was the President, Sir RICHARD QUAIN, absent, but there were several vacant places around the table.

The Health of the President.

Sir DYCE DUCKWORTH said that perhaps he might be permitted in a very few words to express the feelings they all entertained at that moment on seeing the presidential chair unoccupied. They all knew the cause of their President not being there and he was sure they were all deeply sorry for it. They had at all events the satisfaction of knowing that though he was unable to be amongst them yet his mind was clear and keen and he was with them in spirit. He believed that their President was fully aware of every item of business that was down upon their programme and that he would be deeply interested in all they did. This was about the twenty-fifth meeting of the Council at which he (Sir Dyce Duckworth) had been present and he could not recollect a single occasion—and certainly not an opening meeting—at which Sir Richard Quain was not present in his place either as an ordinary member or as President of the Council. That was a remarkable record and they knew that Sir Richard had been for a longer period than that a member of the Council. In his absence he proposed that Sir William Turner, chairman of the Business Committee, occupy the chair. Members would all recognise that Sir William Turner, by his great business capacity, his urbanity, and his great knowledge of the affairs of the Council was well qualified to perform the duties of their chairman.

This proposition having been seconded and adopted Sir William Turner took his place in the chair and the business of the session proceeded.

Introduction of New Members.

Sir CHRISTOPHER JOHN NIXON, the successor of Sir JOHN BANKS in the representation of the Royal University of Ireland, was formally introduced by Dr. Bennett and took his place at the table.

Mr. VICTOR HORSLEY, the new direct representative for England in succession to Dr. Rentoul, was formally introduced by Dr. Glover.

Letter from the President.

Mr. ALLEN, the Registrar, read the following letter which had been received from the President—viz.:—

67, Harley street, London, W.,
Nov. 23rd, 1897.

DEAR COLLEAGUES,—I deeply regret that—though my health is improved—I cannot undertake the risk of presiding at your meetings during the present session, and if it be your pleasure I shall be glad if Sir William Turner, the Chairman of the Business Committee, will discharge for me the duties of the office. Since the last session of the Council, notwithstanding my illness, I have continued, with the valuable assistance of the officials of the Council, to give close attention to its business; and I think you will find on the present occasion that the various matters that will be placed before you are in as complete and forward a state as usual.

To some of the subjects that appear on the programme I should like to draw your special attention. It is a source of great satisfaction to me to be able to announce that some progress has been made with regard to the question of disciplinary or penal powers exercised by the various licensing bodies. Following the example of the University of Cambridge, the University of Durham has now obtained a Charter under which it has the power of taking away any degree from a graduate who has been convicted of a crime for which he has been sentenced to penal servitude or imprisonment. Similar steps, I am informed, are being taken by the Victoria University, its Court having decided to make an application for the necessary amendment of its Charter, so that in a very short time that university also will be in possession of extended powers. In Scotland, also, some further steps have been taken in regard to this question. The Edinburgh University Court has again considered the question of obtaining power to remove from the Roll any graduate who may be found guilty of a criminal offence or other misconduct; and the Court has decided to intimate to the other University Courts that while remaining of opinion that the difficulties of the question are very great it is willing to confer with the other universities and to appoint representatives to a joint committee which might report to the various Courts. The Court of the University of Glasgow also, on July 8th, 1897, adopted a

Digitized by Google

memorandum in which it expressed its willingness to take joint action with the other Scottish Universities, and suggested to the Universities' Commissioners that although the Commissioners regarded the subject of additional disciplinary powers as not within their province it might be possible for them to leave on record in their final report an expression of opinion in regard to it; but in reply the Commissioners appear to have adhered to their former opinion and state that they have no Parliamentary powers to deal with the question nor any instructions to report upon it. The Universities of Aberdeen and St. Andrews will, no doubt, be prepared to adopt a course of action similar to that taken by Edinburgh and Glasgow. There is the one remaining case of the Royal University of Ireland, from which no information has been received as to any steps taken to obtain additional powers.

With regard to the new edition of the British Pharmacopœia, I have much pleasure in informing the Council that the arduous and important work of preparation that has now occupied about three years, is well-nigh finished. The work is now practically complete, every question of principle having been decided; and if the Council will accept the draft which will be placed before them in the course of the present session it will only be necessary to allow a short time for putting into action certain legal details, so that it might be confidently expected that the work may be published at an early date.

The Council will be aware that during the recess Dr. Rentoul, who had been elected as one of the Direct Representatives for England, suddenly resigned, and it became necessary to hold a new election. As many members of the Council were absent from home at the time the arrangements for this as well as the responsibility had to be entirely undertaken by myself. The election resulted, as members know, in the return of Mr. Horsley at the head of the poll.

The number of penal cases engaging the attention of the Council at the present session is larger than usual, but I have no doubt that the Executive Committee will be able to arrange that the hearing of these cases may interfere as little as possible with the consideration of educational and other equally important subjects. The question of medical aid associations has received the careful attention of the committee appointed to consider it. A report on the subject will be submitted to the Council, the evidence obtained by the committee having been already placed in your hands. Other important reports will also be presented by the Education Committee on the subject of preliminary examinations, by the Executive Committee on the resolutions of the Council in regard to the employment of unqualified assistants, and by the Dental Education and Examination Committee in regard to the recommendations of the Council to the dental licensing bodies.

Again expressing my regret at not being able to be with you at this session—the first from which I have been absent during a period of thirty-four years—and trusting that I have clearly indicated the nature of the business to be brought before your attention,

I remain, yours faithfully,

RICHARD QUAIN.

The CHAIRMAN said the members were aware that it had been the habit of the President to open the business of the session with an address, and that after the address had been delivered it had been moved that it appear on the minutes. This always had been agreed to. They had not to-day an address from the President, but they had the communication which had just been read, and he felt sure that he was speaking the sentiments of the Council when he proposed that this communication should appear upon the minutes. He should like to say that as chairman of the Business Committee he had been during this month and a portion of last in frequent communication with the President as to the arrangement of the business and he should like to bear out the statement that the President's mind was as intellectually active as ever it was and that he had got a thorough grasp of all the details of the business that had to come before them on this occasion. He should like also to state from the chair that he was sure the Council would deeply sympathise with the President in his enforced absence and in his prolonged illness. He moved that this communication be entered on the minutes.

Mr. TEALE seconded the motion, and it was at once adopted.

On the motion of Sir DYCE DUCKWORTH, seconded by Mr. BRUDENELL CARTER, it was agreed—

That in accordance with the desire of the President, expressed in his communication to the Council, Sir William Turner, the chairman of the Business Committee, be requested to discharge during the present session the duties of the chair.

The Service Examinations.

Statistical tables were received showing results of competitions—(*a*) for commissions in the medical department of the Royal Navy, held on May 17th, 1897; (*b*) for commissions in the Medical Staff of the Army, held in August, 1897; and (*c*) for commissions in the Indian Medical Service, held in July, 1897.

Dr. HERON WATSON, seconded by Sir RICHARD THORNE, moved:—

That the thanks of the Council be conveyed to the Director-General of the Medical Department of the Royal Navy, to the Director-General of the Army Medical Department, and to the Examining Board of the Medical Department of the Indian Medical Service for the statements they have respectively furnished to the Council of the degrees, diplomas, and licences of the candidates for commissions in those departments of Her Majesty's Service of the dates mentioned, showing the numbers of vacancies to be competed for, the numbers that did and did not pass, the number obtaining commissions, distinguishing the qualifications, both medical and surgical, under the several licensing bodies, and indicating the subjects in which those who did not pass were found to be deficient; with the request that these returns may in future be continued to be furnished to the General Medical Council.

Dr. GLOVER pointed out that the returns were conspicuous for the want of information as to the number of vacancies competed for. If they were to believe the newspapers the state of the Army Medical Department was alarming, and he thought that this Council was one of the bodies which should have most immediate, complete, and specific information as to the point. Therefore, although he did not propose to move any amendment, he could not thank the Director-General of the Army quite so much as he would have done had he given the Council a little more light. Perhaps a request might be made for more information on this particular point. As to the general information given it seemed to him very satisfactory. Judging from the rejections it did not appear by any means that men of inferior character came before either the navy or the army medical authorities.

Dr. HERON WATSON reminded Dr. Glover and the Council generally that these returns were a matter of favour and not of right. As to what they contained he thought that a good deal might be read in between the lines, and he could not help thinking that the returns might be of considerable value to the inspectors of examinations.

The motion was then agreed to.

Preliminary Education.

Dr. HERON WATSON, seconded by Sir RICHARD THORNE, moved:—

That it be remitted to the Examination Committee of the General Medical Council to consider and bring up a report during the present session upon the letter of date June 16th of the present year from the Director-General of the Army Medical Department, in which he conveys to this Council the expression of his regret that he is unable to accede to the request (namely, that he should notify to this Council where the preliminary examination in Arts has been passed and the date of such preliminary examination of any candidate who may have evinced marked deficiency in preliminary education on the occasion of his examination for admission to the Army Medical Department), as there are, to his mind, serious objections to dealing with this subject in the manner proposed.

Dr. Heron Watson said that in the letter there was an indication of what probably was the source of the objection of the Director-General, and he thought it would be well to have the matter discussed in committee in the first instance.

Sir DYCE DUCKWORTH said it would be a matter of considerable interest and usefulness if the Council expressed an opinion on this subject. The point was that this Council wished to reach the bodies who passed candidates in preliminary arts examinations under what must obviously be very insufficient conditions, and very few opportunities presented themselves of ascertaining what those conditions really were unless they had to deal with the examinations of candidates who had already got diplomas. The examining bodies entirely washed their hands of all responsibility in the matter and threw it upon the General Medical Council. They told the Council that it was its business to see that the candidates who enter the medical profession were properly prepared by undergoing a liberal education. If the Council put them upon the Register as medical students the bodies washed their hands of all further responsibility as to the general educational attainments of the candidates who presented themselves. They had thought that by discovering defects in candidates either for the Navy or the Army or the Indian Service they might bring home to the bodies that the examinations these candidates had passed must be of an inferior order. Some of the candidates sent in papers that were perfectly disgraceful, showing that any best in their case must have been altogether inadequate. They wished to get from the army and navy authorities some clue by which to reach the bodies who passed such candidates, and he was sure the examination committee would be glad to know what was the feeling of the Council on the matter. He thought the Council should go into the matter and that it was its business to investigate and supervise and be thoroughly satisfied as to the quality of the preliminary examinations.

Dr. MACALISTER endorsed what Sir Dyce Duckworth had said, adding that the Council ought to be able to trace the source of the preliminary education. At present they were hampered by some scruple on the part of the Director-General, but he thought that they should make another and vigorous effort to get at the root of the matter.

The motion was then adopted by the Council

The Employment of Unqualified Assistants.

The Council agreed to receive and enter upon the minutes the following Report from the Executive Committee on the Council's resolutions on the employment of unqualified assistants pursuant to the following resolution:—

That it be referred to the Executive Committee to consider whether the Council's resolutions on the employment of unqualified assistants, as they appear in the advertisements inserted in the medical journals, may not with advantage be rendered clearer and more stringent.—Minutes, vol. xxxiv., p. 90.

REPORT BY THE EXECUTIVE COMMITTEE ON THE GROWTH OF OPINION OF THE GENERAL MEDICAL COUNCIL IN REGARD TO THE EMPLOYMENT OF UNQUALIFIED ASSISTANTS AND ON "COVERING UNQUALIFIED PERSONS."

(Prepared by Mr. BRYANT)

(1) On April 21st, 1883 (Minutes, vol. xx., p. 91), the General Medical Council passed the following resolution as proposed by Dr. CHAMBERS and seconded by Mr. SIMON:—

That the following resolutions, passed by the Council in Committee, be received and adopted:—

(*a*) That the Council ask for legislation to the effect that any registered practitioner practising for gain, who knowingly and wilfully deputes a person not registered or qualified to be registered under the Medical Act to professionally treat on his behalf, in any matter requiring professional discretion or skill, any sick or injured person, shall be subject to the same legal liabilities as a person who falsely represents himself to be a legally qualified medical practitioner, but with special proviso that such enactment shall not hinder any duly regulated training of pupils in medical schools or otherwise by legally qualified practitioners, nor the use of trained pupils in partially treating the sick or injured under the direction, supervision, and responsibility of such practitioners, nor any legitimate employment of nurses, midwives, or dispensers.

(*b*) That communications be entered into by the Council with the Registrar-General with the view of procuring such amendments of the Registration Act of England as will diminish the present frequent evasions of the Act in the certification of causes of death.

(*c*) That the Council record on its minutes, for the information of those whom it may concern, that charges of gross misconduct in the employment of unqualified assistants, and charges of dishonest collusion with unqualified practitioners in respect of the signing of medical certificates required for the purposes of any law or lawful contract, are, if brought before the Council, regarded by the Council as charges of infamous conduct under the Medical Act.

(2) On Nov. 20th, 1886, the Council determined that steps be taken with a view of making the above resolution more public; accordingly, on July 25th, 1887, the Executive Committee ordered it to be inserted twice at an interval of a month apart as an advertisement in the medical journals.

(3) On Nov. 24th, 1887, a case of the misemployment of an unqualified assistant was brought before the notice of the General Council and adjudicated upon; and the registered practitioner concerned, having been informed of the grave disapprobation with which the Council regarded his conduct, promised at once to discontinue the practice condemned.

(4) On Nov. 26th, 1887, the General Medical Council passed the following resolution:—

That it be referred to the Executive Committee to consider under what circumstances a registered medical practitioner would render himself liable to the censure of the Council in reference to the employment of unqualified assistants.

(5) On Feb. 27th, 1888, the Executive Committee, pursuant to this resolution, without attempting to make a formal definition of the misconduct in question, reported to the General Council that, in its opinion,—

A registered medical practitioner would render himself liable to the censure of the Medical Council in case of the employment of an unqualified assistant in the practice of medicine, surgery, or midwifery on behalf and for the benefit of such registered practitioner, either in complete substitution for his own services or under circumstances in which due personal supervision and control are not, or cannot be, exercised by the said registered practitioner.

The Executive Committee also stated, in reference to the procedure known as "covering," that in its view a registered practitioner covers an unregistered person when he does, or assists in doing, or is party to, any act which enables such unqualified person to practise as if he were duly qualified.

(6) On May 24th, 1888, the Council found and declared that the offence of "covering" had been proved against a practitioner brought before it; but on the defendant's admission that he had inadvertently committed that offence, his statement that he had discontinued the practice, and his promising not so to offend again the Council passed thereon this further resolution:—

That A—— B—— having expressed his contrition at having followed a course of conduct which the Council had declared to be most gravely wrong, and having stated that he had altogether ceased to pursue, and would pledge himself not to resume such conduct, and having then prayed for a merciful consideration of his case by the Council, the Council, in view of all the circumstances of the case, does not see fit to proceed further in the matter beyond requesting the President to admonish him most seriously.

The President communicated to A. B. the foregoing resolution and also admonished him seriously as to the exceeding gravity of his conduct.

(7) In November, 1888, four other cases were brought under the notice of the General Council, and the offence of "covering" having, after careful consideration, been proved in two of the cases, the names of the two practitioners thus found guilty of "infamous conduct in a professional respect" were, by the Council's orders, erased from the Medical Register.

(8) In May, 1891, the General Council directed the removal from the Medical Register of the name of a practitioner who had been summoned to appear and was found guilty of infamous conduct in a professional respect on the following charge:—

That he had continuously throughout the year acted as cover to a person who was not registered or qualified to practise as a registered medical practitioner, that is to say, that he had in concert with the said person, and by permitting him the use of his name, enabled him improperly to practise and sign medical certificates as if he had been a duly qualified registered medical practitioner.

(9) In November, 1891, two practitioners were also summoned, and after consideration their names were respectively erased from the Medical Register on the following charge:—

That he, being a registered medical practitioner, caused and enabled a medical practice to be improperly carried on in his name and for his benefit by means of the employment of an unqualified person, in which medical practice so carried on there was gross misconduct and culpable neglect of patients.

(10) In May, 1892, the General Council directed the removal from the Medical Register of the names of two practitioners who, having been summoned to appear, were found guilty of infamous conduct in a professional respect on the following charge:—

That they systematically permitted and enabled an unqualified person, under cover of their names and qualifications, to attend and prescribe for patients on his own responsibility in all respects as if he were duly qualified, to the detriment of persons who applied for medical aid at the places where such medical practice was carried on.

(11) In November, 1893, a registered practitioner was found guilty by the General Council of infamous conduct in a professional respect and his name erased from the Medical Register on the following charge:—

That, being a regular medical practitioner, he had continually during the years 1891 and 1892 acted as cover of and by his presence and assistance had enabled an unqualified person to carry on a medical practice as if he had been duly qualified.

Also that during the period aforesaid he habitually signed and gave certificates of vaccination, illness, and death in cases in which the said person had attended and he had not attended, and empowered the said person to sign his name to such certificates in cases attended by the unqualified practitioner and not by him, thereby enabling him to practise as aforesaid.

(12) On May 26th, 1893, the Council, after considering the report of the Medical Aid Associations Committee, passed a resolution to the effect that the rules already laid down by the Council as to "covering" unqualified assistants should apply to medical officers of medical aid associations in respect of any unqualified persons whom an association may have engaged to assist them (vol. xxx., p. 64).

(13) In May, 1894, three further cases were considered by the General Council of registered practitioners who had lent their presence, advice, and assistance to enable unqualified persons to attend patients and recover charges therefore as though legally qualified, and after they had been summoned before the Council and, the charges proved, their names were erased from the Medical Register.

(14) On Nov. 27th, 1896, a practitioner from Wales was summoned before the Council for the offence of covering, when the President informed him that the charge had been proved to the satisfaction of the Council and that the services of all unqualified assistants must be dispensed with, and further stated that the Council wished it to be known by all practitioners in the district that the employment of such assistants in the practice of medicine, surgery, and midwifery would meet with its strong condemnation.

(15) On Nov. 27th, 1896 two practitioners from the county of Durham were summoned before the Council on charges of covering, when it was made clear to the Council that in this colliery district the custom of employing unqualified assistants was not only general but that the district registrar of that part of the country habitually received from unqualified persons "notes or information" informing him

Digitized by Google

of the fact and cause of death and completed the registration in respect of the cause of death in the register without requiring a certificate of the cause of death signed by a registered medical practitioner; and, moreover, that this "information" was used in extracts granted to club officials in order that their members might obtain their club money.

(16) The General Medical Council having now had this question of the illegitimate employment of unqualified assistants before them for fourteen years, and that of "covering unqualified persons" for more than ten years; and having, by frequent advertisements in the medical papers during these last ten years, by censures in some cases and removals from the Register in other cases of a graver nature, proved to the members of the medical profession their entire disapproval of the employment of an unqualified assistant in the practice of medicine, surgery, or midwifery on behalf and for the benefit of such registered practitioner either in complete substitution for his own services, or under circumstances in which due personal supervision and control are not, or cannot be, exercised by the said registered practitioner (Feb. 27th, 1888); and having also made it widely known that they regard the practice of "covering" as "infamous conduct in a professional respect,"—the procedure known as covering having been defined by the Executive Committee as follows: "That, in its view, a registered practitioner *covers* an unregistered person when he does, or assists in doing, or is party to, any act which enables such unqualified person to practise as if he were duly qualified" (Feb. 27th, 1888),—

The Council now give notice that on and after Jan. 1st, 1900, the employment of any unqualified assistant in the practice of medicine, surgery, and midwifery will be treated as an offence under the Medical Act, and may be regarded as "infamous conduct in a professional respect," but with special proviso that such resolutions "should" not hinder any duly regulated training of pupils in medical schools or otherwise by legally qualified practitioners, or the use of trained pupils in partially treating the sick or injured under the direction, supervision, and responsibility of such practitioners, or any legitimate employment of nurses, midwives, or dispensers.

May, 1897. T. BRYANT.

APPENDIX.

Amendment of the Resolutions of the General Medical Council on the Employment of Unqualified Assistants as formulated by Dr. MACALISTER at the request of the President.

NOTICE.

EMPLOYMENT OF UNQUALIFIED PERSONS AS ASSISTANTS OR OTHERWISE.

Whereas it has from time to time been made to appear to the General Medical Council that some Registered Medical Practitioners have been in the habit of employing as assistants in connexion with their professional practice person who are not duly qualified or registered under the Medical Acts, and have knowingly allowed such unqualified persons to attend or treat patients in respect of matters requiring professional discretion or skill, and whereas in the opinion of the Council such a substitution of the services of an unqualified person for those of a registered medical practitioner is in its nature fraudulent and dangerous to the public health, the Council hereby gives notice that any registered medical practitioner, who is proved to have so employed an unqualified assistant is liable to be judged as guilty of "infamous conduct in a professional respect" and to have his name erased from the Medical Register under the 29th Section of the Medical Act, 1858.

Further, in regard to the practice commonly known as "covering," the Council gives notice that any registered medical practitioner who, by his presence, countenance, advice, assistance, or coöperation, knowingly enables an unqualified or unregistered person (whether described as an assistant or otherwise) to attend or treat any patient, to procure or issue any medical certificate or certificate of death, or otherwise to engage in medical practice as if the said person were duly qualified and registered, is liable to be judged as guilty of "infamous conduct in a professional respect" and to have his name erased from the Medical Register under the said enactments.

But the foregoing notices do not apply so as to restrict the proper training and instruction of *bonâ fide* medical students and pupils or the legitimate employment of dressers, dispensers, and surgery attendants under the immediate personal supervision of registered medical practitioners.

The Executive Committee having considered this subject as set forth in the foregoing statement on the growth of opinion in regard to it, and having considered also the proposed alteration of the Council's resolution drafted by Dr. MacAlister and entered in the appendix, directed that paragraph 16 of the foregoing report should be published annually in the medical journals in lieu of that now inserted.

Mr. BRYANT at the request of the CHAIRMAN read in full the portion of the report to which his signature was attached.

Dr. MACALISTER then read the appendix. He explained that having gone through Mr. Bryant's memorandum on the action of the Council he drew up the appendix and sent it to the President, who made some suggestions. Thereafter it was submitted to the lawyers of the Council, who accepted it with one or two verbal alterations. Then it went to the Executive Committee and this committee had apparently not reported upon it but had merely given it as an appendix to their report. He did not see how paragraph 16 of Mr. Bryant's memorandum could be regarded in the character of a notice and used as such because it could not be read without some context which was not supplied. Therefore he preferred the notice in the appendix.

The CHAIRMAN pointed out that the last paragraph in the report mentioned a date which the appendix did not. He thought there surely should be some notice or warning given.

Dr. MACALISTER said he was not at all sure about the warning because everything dealt with in this notice had been dealt with by this Council; there were precedents for every case that would come under this notice in the previous action of the Council. It was an unmistakable statement of their present stand in the matter that was wanted rather than any extension of legislation, and in that case he saw no need for notice. He moved: "That the notice to be inserted as an advertisement in the medical journals be that set forth in the appendix to the Executive Committee's report."

Dr. BRUCE seconded this motion.

Mr. TEALE said he was strongly in favour of the proposition in the report to name the first day of the year 1900 because he could not help regarding this as a new departure. In the previous definitions of the Council they had left a considerable margin between what was legitimate and what was illegitimate. He thought, too, that the matter of pupilage would have to be dealt with, and if necessary he would propose a rider to the motion.

Sir RICHARD THORNE said it seemed to him that in some respects Dr. MacAlister's motion was distinctly clearer than the proposal which stood above the signature of Mr. Bryant, because the latter implied that up till 1900 the Council would go back upon its present practice in regard to these matters.

Mr. BROWN said that having regard to the present practice of the Council he did not see any necessity for giving notice. The Council would be able to consider the merits of each case as it came up, and if mercy should be shown then no doubt it would be shown. He thought something should be inserted relating to the employment of midwives.

Dr. LOMBE ATTHILL supported the view that dates should be left out of the motion altogether.

Dr. HECTOR CAMERON, as the member who seconded the resolution by which this subject was referred to the committee, agreed entirely with Dr. MacAlister that the notice which the latter had drawn up was much more explicit and clearer than that which the Executive Committee proposed to advertise. But he further agreed with Mr. Teale that they ought to do two things. They ought to allow a little time before their intention became operative and they ought to make it clear what really was a pupil in contra-distinction to an assistant. What made it necessary for them to allow time was that the Council approved of the employment of unqualified assistants where such employment did not mean "covering." When that was so practitioners who had unqualified assistants should be allowed a year or two to make arrangements for carrying on their business. He should be disposed to support such a rider to the motion as Mr. Teale had drafted.

The CHAIRMAN thought it was as well that the Council should hear what the proposed rider was. It was this:—

That the decision and definition of the Council be issued to every medical practitioner on the Register and that the definition of a "pupil-assistant" as approved by the Council be: A medical student in whose case not more than six years has elapsed since his registration as a medical student.

The Council would need to pass Dr. MacAlister's motion before they dealt with this rider.

Dr. MCVAIL considered that the rider made more definite what Dr. MacAlister required in the last paragraph of his proposal. That was to say, he defined a medical student in such a way as to make it clear what a *bonâ-fide* medical student was. If Dr. MacAlister accepted the rider he (Dr. McVail) thought they might unanimously take the motion, after accepting which they could consider the question of the year in which it should become operative.

Dr. MACALISTER wished the motion to be taken on its own merits.

Mr. BRYANT liked Dr. MacAlister's motion better than the paragraph 16 which the Executive Committee suggested should be advertised, and he looked upon the proposed rider

Digitized by Google

as also remarkably good in so far as it admitted no man to act as an unqualified assistant after his name had appeared for more than six years in the Students' Register.

Sir RICHARD THORNE asked Dr. MacAlister to explain why "midwives" did not appear in his motion seeing that the term occurred in the original resolutions of 1883.

Dr. GLOVER wished to know whether Dr. MacAlister was prepared to differentiate between pupil and unqualified assistant.

Dr. MACALISTER, in reply, adverted to an objection taken to the term "unqualified or unregistered person." He pointed out that there were some persons—lawyers—who held that "qualified" and "registered" were not synonymous, and therefore it was necessary to use the two words. With regard to "midwives" he thought that word was in his original draft of the motion and must have dropped out in the course of revision by their President and legal adviser. He saw no reason why "midwives" should not be in and he should now ask that the word be inserted. With regard to pupils the motion had it that the notices were not to apply so as to restrict the proper training and instruction of *bonâ-fide* medical students and pupils. Clearly a distinction of a practical kind between pupil and unqualified assistant was whether the man paid for his instruction or was paid for his work. That seemed to him to be a practical test, but he could not put it in his motion, which he should like to see accepted. If the Council did pass it they could consider the question of the time at which it should become operative.

The motion was amended by the insertion of the word "midwives," and on then being put was carried unanimously.

The CHAIRMAN said they had now to deal with Mr. Teale's proposed rider, but it seemed to him that it consisted of two distinct parts, and that the second, which contained the definition referred to in the earlier, should be first dealt with.

Dr. MACALISTER wished to point out that it was proposed to define a word which did not occur in the resolution just passed. What was a pupil-assistant?

Dr. BATTY TUKE suggested that to make such an alteration as the definition proposed would land them in a somewhat dangerous position. The average number of years between registration as a student and as a practitioner was six and a half, and if six years were, as proposed, adopted now they would be interfering with the average student.

Dr. GAIRDNER'S opinion was that six years was a matter that required very much attention.

Dr. LEECH said that the adoption of such a period would cut off very many of their best men who in the middle of the course went two or three years to science and then returned to complete the medical course. It would be a great mistake to accept the proposal.

Sir RICHARD THORNE suggested that seven years should be substituted for the six proposed.

Mr. TEALE and Dr. HECTOR CAMERON were quite willing to accept this suggestion.

Sir PHILIP SMYLY looked upon the rider as proposing something contrary to the Council's regulation permitting six months of the fifth year of study to be spent with a registered practitioner. Surely nothing should be done that would interfere with that regulation. He objected altogether to the use of the term "pupil-assistant," which had never been used before.

On the motion of Dr. BATTY TUKE the debate was adjourned.

The Council adjourned.

WEDNESDAY, NOV. 24TH.

The Council resumed to-day, Sir WILLIAM TURNER acting as chairman.

The President's Health.

Mr. H. E. ALLEN, the Registrar, read a letter, dated Nov. 24th, from Sir Richard Quain, asking him to be so good as to express to the Council the President's feeling of heartfelt gratitude for the previous day's resolution of sympathy with him which had been a source of much comfort. The President was happy to say that he was much better since his return from the country a few weeks ago.

On the motion of Mr. BRYANT, seconded by Dr. BRUCE, the communication was entered on the minutes.

Resignation of Dr. Wm. Moore.

The CHAIRMAN said that he had received a communication from the President on another subject. The Council would have noticed the absence of Dr. William Moore, one of the Irish representatives. Dr. Moore was in very bad health. He had intimated to the President some time ago that he feared he would have to retire from the Council, but at that time he had not actually intimated that he did retire. Dr. Moore had since been telegraphed to on the subject, and a telegram had been received in reply which the President took to intimate his resignation. The appointment of a successor lay with the Privy Council, to whom the resignation had been made known.

Employment of Unqualified Assistants.

Mr. BRYANT stated that he wished to correct the last paragraph of the Executive Committee's report in regard to the employment of unqualified assistants by the insertion of the word "formally" so as to make the first line read:—"The Council now formally give notice," &c.

Dr. MACALISTER wished to correct a mistake in the last paragraph of the "notice" which had been adopted by the Council. The word "and" between the words "*bonâ-fide* medical students" and "pupils" should be not "and" but "as."

Debate was resumed on that portion of Mr. TEALE'S rider to Dr. MACALISTER'S resolution which was under discussion at the adjournment on Tuesday, viz.:—

That the definition of pupil-assistant, as approved by the Council, be—"a medical student in whose case not more than seven years have elapsed since his registration as a medical student."

Dr. BATTY TUKE said he objected to this definition because it would exclude a certain number of medical students from a line of study which was approved of by the Council. The average period of medical students' study was six and a half years, and a table which he held in his hand showed that a considerable number of men took more than seven years to complete their course. He thought it was extremely dangerous to attempt to define in the present instance. It was absolutely impossible for them to foresee what possible dodges and subterfuges would be introduced to get behind such a definition as that proposed. It seemed to him that the position was sufficiently well-guarded in the "notice" which it was proposed to send out to the medical practitioners of the country. That declared that, "Whereas it has from time to time been made to appear to the General Medical Council that some registered medical practitioners have been in the habit of employing as assistants in connexion with their professional practice persons who are not duly qualified or registered under the Medical Acts, and have knowingly allowed such unqualified persons to attend or treat patients in respect of matters requiring professional discretion or skill." He thought that sufficiently defined the position. The correction made by Dr. MacAlister a few minutes since was intelligible and satisfactory, but the question would arise as to what a *bonâ-fide* student was. For his part he thought a definition would be arrived at by the decision given in a case or cases that would come before the Council. Meantime he objected to the term "pupil-assistant." It was entirely new and was one which in itself was dangerous. For such reasons he could not vote for Mr. Teale's proposal.

Mr. BROWN: Do you propose an amendment?

Dr. BATTY TUKE: No.

Sir CHRISTOPHER NIXON quite agreed with Dr. Tuke in objecting to the introduction in the proposal of a new term. He thought that as it stood at present the term "pupil-assistant" was simply a synonym for "unqualified assistant" and because of that it seemed to him to be very objectionable. He took the strongest view that this Council should do all in its power to stop the notoriously infamous practice of employing unqualified assistants, and what he was afraid of was that if the rider was adopted it would simply provide facilities to enable practitioners to proceed in the very line of conduct which the Council condemned because they would provide the general practitioner with assistants which they recognised in the most formal way. If they established a rule allowing the employment of pupil-assistants for two years he did not think they would be able to obtain the conviction of any man for the use of students as assistants unless they had it clearly defined that the students did not work for salary.

Digitized by Google

Dr. MCVAIL was prepared to support the rider almost for the very reasons that were to induce Sir C. Nixon to vote against it.

Dr. ATTHILL, who intended to support the rider, asked if it would be possible to alter the term "pupil-assistant" which did not appear in the resolution adopted on Tuesday. He suggested that they should take "registered medical student" instead.

Dr. MACALISTER thought that in future a man would have to produce a great deal of proof before they believed that an unqualified assistant was only a student. The last clause of the resolution the Council had adopted was not one for allowing students up to seven years of studentship to go as assistants. The clause was a negative one. It said unqualified assistants would not be allowed, but it did not put any restriction on the instruction of students; it did not encourage the use of students for the purpose of gain. If a practitioner alleged that his assistant was a student he would have to prove it. The onus of proof should be on him and the Council should not in any way assist him to prove his allegation. A great many unqualified assistants were not students, but if the rider proposed were adopted what was to prevent any of these men entering themselves as students to-morrow and thus getting seven years in which they might assist a practitioner, who at the end of that period would find another man to register and act with him for another seven years? The rider would manufacture a supply of the men they wanted to get rid of. They should avoid the mistake Parliament found it had made in providing that the *bonâ fide* traveller was a man who had walked four miles. They should leave definition alone at present and let the *bona fides* be proved when a case came before them.

Mr. BRUDENELL CARTER agreed that the best way of dealing with this question was to leave it in such a state of indefiniteness that the discretion of the Council should be exercised on every case that arose.

Dr. GLOVER, while feeling that it was very difficult to arrive at a satisfactory definition of the kind of pupil that they approved and the kind that they disapproved, could not agree with Mr. Carter in prolonging indefiniteness. There should be some definition. If there was to be any improvement in the Council's penal procedure—if there was to be any effective stop put to a great evil—there must be precision of language in their pronouncements. That they should furnish such precision would not only be just to the practitioner but kind to the student. He did not think the period of seven years the rider provided was long enough, but if they made it ten years that would remove a great deal of the objection to the proposal.

Sir RICHARD THORNE said that he suggested on Tuesday that the period should be lengthened from six years to seven, but he was bound to say that as a result of the discussion of to-day he would rather not vote on the proposal at all.

Dr. GAIRDNER would rather not have the rider at all. He agreed that they should leave each case to be decided on its own merits. The time limit in his view was a hopeless one.

Sir WILLIAM THOMSON was prepared to contend that as soon as a fifth-year student completed his six months' instruction under a registered practitioner he became an unqualified assistant, and there would be a certain amount of protection to the public and the profession if this were set out properly by the Council. The "notice" did not sufficiently do what was necessary.

Mr. HORSLEY felt that he ought not to give a silent vote against the rider. He felt very strongly as had been said by other members of the Council that they were discussing something which did not exist, viz., the pupil-assistant. If that were so he suggested that the discussion was hardly in order. At any rate he would deprecate the further discussion of such a thing as a pupil-assistant. But he thought that the general practitioner should have some help in understanding the paragraphs of the "notice." Accordingly he would suggest that when they came to discuss the second part of the rider Mr. Teale should accept a modification to the effect that the decision of the Council and an explanatory statement relating thereto should be furnished to every practitioner on the Register. That, he thought, would be only just to all concerned.

Mr. TEALE said he felt that the Council were now taking a new departure. If they read the original resolutions of 1883 he thought that they would agree with him that that was so. They were now going to say that practitioners should not use unqualified assistants at all and were trying to draw the line between unqualified assistants and pupils. When they were taking this new departure he was anxious that the Council should let the profession know what they wanted. It had struck some of them that they might draw the line between the students and the unqualified practitioner in some such way as he had suggested, but he must say that although he was proposing this motion he was now convinced that they would land themselves in difficulties if the Council passed it. Therefore if the Council allowed it he would withdraw the proposal.

No objection being raised, the proposal was then withdrawn.

Mr. TEALE thereupon moved:

That the "notice" adopted by the Council in reference to the employment of unqualified assistants be issued to every medical practitioner on the Register, and that a copy thereof be given to every person who is about to have his name entered upon the Medical Register.

He said that the Council's notice at present was by advertisement. He himself had neither seen it in the medical journals nor had he read it, and he believed many members of the profession had like himself never seen it. Consequently, when men were before the Council and pleaded ignorance he had felt that they had rather a strong point against the Council for not taking the proper means to make the profession acquainted with their wishes and requirements.

Sir DYCE DUCKWORTH had some sympathy with this view. Their advertisement ought to get a better place in the medical journals than was given to it.

The proposal was adopted.

Mr. TEALE next moved:

That when the announcement of the decision of the Council as to the entire disuse of unqualified assistants, with the exception as to the instruction of *bonâ-fide* medical pupils, an intimation be issued that the Council will act on this decision in any case which occurs after Jan. 1st, 1900.

Dr. CAMERON seconded.

Dr. GAIRDNER could not see any reason for making any limit at all. They had declared that a certain thing was fraudulent and dangerous to the public. Were they to say that they were going to give a close time up to 1900?

Mr. TEALE felt strongly that as they were taking a new departure they ought to take the course suggested in his motion.

Dr. MACALISTER absolutely objected to any time limit. They did not require to give notice. They could deal with bad cases now and they could begin to deal with fresh cases that might arise under the new "notice" when they liked.

Dr. CAMERON pointed out that in proposing 1900 the movers were only following the course suggested by the Executive Committee.

Dr. MACALISTER: But that was not adopted.

After a few remarks by Dr. BRUCE, the Council divided, when 3 voted for the motion and 23 against it. The motion accordingly was rejected.

Members' Speeches.

On the motion of Dr. MACALISTER, the Council received and entered on the minutes a report from the Executive Committee, which stated that the committee had considered the resolution of May 31st, and were not prepared at this time to recommend the Council to adopt a standing order to limit the length of speeches. The resolution in question was as follows:—

That it be referred to the executive committee to consider and report whether it would be desirable for the Council to adopt a standing order to the effect that no member of the Council, other than the President or the chairman of a committee introducing a report, shall speak to any motion for more than ten minutes without the permission of the Council being asked from the chair, and granted by resolution moved, seconded, and put without debate.

AN INFORMAL PETITION.

On the motion of Dr. MACALISTER the following report was received and entered on the minutes:—

The Business Committee beg leave to report as follows:

They have had laid before them copies of a petition headed "Registered Practitioners of Great Britain and Ireland to the General Medical Council," signed by fifty-three persons in all. Under Standing Order VII., 16, "No petition shall be received by the Council which is reported ..... to refer to more than a single main question." The

Digitized by Google

petition under consideration refers to ten or more main questions relating to the powers of the Council, to the ethics of the medical profession, and to proposals for medical legislation in various directions. The Committee accordingly report that the petition is not in accordance with the standing orders and is thus excluded from being received by the Council.

Mr. BROWN, suggesting that the petition must have been drawn up in ignorance of the standing orders, asked the Council to waive their standing orders in this instance and receive a deputation from the petitioners, who would address themselves to one single main question.

Sir WILLIAM THOMSON seconded a formal motion to that effect which Mr. Brown handed to the chairman.

Dr. MACALISTER objected that this motion consisted of two parts. A motion for the suspension of standing orders ought to be a separate proposal.

Mr. BROWN moved that the standing order that prevented the petition being received be suspended.

The original proposal was not withdrawn and this new one was not seconded.

Sir RICHARD THORNE thought the procedure in the case was most inconvenient. They were, he said, proceeding to suspend a standing order on a matter of which they knew nothing.

Mr. BRUDENELL CARTER pointed out that there was nothing before the Council about receiving a deputation.

The REGISTRAR, in answer to Mr. Brown, said that a letter asking that a deputation should be received had reached him, but the time had not arrived for considering it. It must be dealt with by the business committee.

Dr. MACALISTER hoped the Council would not suspend the standing order. If any number of practitioners had a grievance on which they wished to address the Council on a single point the Council were willing to receive them. But in this case it seemed to him that the first thing the petitioners should have done was to inform themselves as to what were the Council's standing orders in the matter.

As only two members voted in support of it Mr. Brown's proposal was rejected.

An Application for Restoration to the Register.

The following report was brought up:—

The Executive Committee have considered the application of John Melvin Campbell, Lic. Soc. Apoth. Lond. 1873, whose name was removed from the Medical Register on May 23rd, 1894, and have ascertained that the applicant has complied with the standing orders. The Committee, having considered the case and accompanying certificates, recommend the General Council to restore the name and qualification of John Melvin Campbell to the Medical Register.

Mr. BRYANT moved the adoption of the Committee's recommendation, and Mr. BRUDENELL CARTER, in seconding, said that he felt at the time the name of Mr. Campbell was removed from the Medical Register that the case was of such a kind that his name might be restored in two or three years. He had communicated his impression to the Apothecaries' Society so that they might leave him in such a position that he might apply for restoration. Mr. Campbell still possessed the qualification.

Mr. HORSLEY drew attention to the difference of procedure adopted by licensing bodies in cases such as that before them.

Mr. BRUDENELL CARTER stated that the Licentiates of the Apothecaries' Society stood in a different position from those of many other licensing bodies. The Apothecaries' Society, although having the power to remove a qualification, had no power to restore it. Other bodies could restore a qualification that had been removed.

Dr. MACALISTER remarked that the only thing the Society could do was to strike a man's name off the list of Licentiates. That had been done in this case, as in reply to a letter from the Council's registrar, Mr. Upton, of the Apothecaries' Society, had replied that the name of Mr. Campbell was struck off the list of the Society's Licentiates on June 21st, 1894.

Dr. BATTY TUKE said there was something mysterious about this case. They did not know all the facts. The executive committee were not aware that the man's name had been struck off the list. Was the executive committee going to recommend that a man without a qualification at all was to be put on the Medical Register?

The CHAIRMAN pointed out that Mr. Upton's letter also stated that although Mr. Campbell's name had been removed from the list of Licentiates he still held the Society's qualification, the Society having no power to cancel a qualification.

Mr. BROWN suggested that the Society should move first in this instance, and restore Mr. Campbell's name to their list of Licentiates.

Mr. BRUDENELL CARTER: They cannot do it.

The CHAIRMAN: By the Act power is given to strike off from the list of Licentiates, but no power is given to restore.

Mr. HORSLEY: What justification is there for Mr. Upton's statement that a man may still retain his qualification although his name is removed from the list of Licentiates?

Dr. MACALISTER thought they should not proceed further with this case until their legal adviser was present.

This seemed to be the feeling of the Council and the usual adjournment for tea then took place.

When business was resumed Mr. CARTER made a further short statement with regard to the legal position of the Apothecaries' Society in relation to its Licentiates.

The Case of Robert Masters Theobald.

The Executive Committee reported that having considered the application made by Robert Masters Theobald to be restored to the Medical Register from which his name was removed on Dec. 3rd, 1894, they recommended the Council that, as he had no registrable qualification, it was not in the power of the Council to restore his name to the Medical Register.

Mr. BRYANT, seconded by Dr. MACALISTER, moved the adoption of the recommendation. The former stated that in this case the diploma had been given up so that no question arose.

The recommendation was agreed to.

The Midwives Question.

The REGISTRAR read the following report on this subject—viz.:—

The Executive Committee inform the Council that they have received the following report from the Midwives Registration Bill Committee:

"The Midwives Registration Bill Committee beg leave to report to the Executive Committee that, having regard to the letter from the Privy Council Office of Nov. 20th, 1897, they are of opinion that there is no necessity for them to submit any observations to the Council on the Bill of last session.

"They are further of opinion that it is desirable that the Council should appoint a committee to report on any Bill for the registration of midwives that may be introduced during next session of Parliament and that may be referred to the Council by the Government.

"Nov. 22nd, 1897." "RICHARD T. THORNE, Chairman.

On the motion of Mr. BROWN there was added to the report the letter of Sir Charles Lennox Peel, which was to this effect: "I have submitted to the Lord President of the Council your letter of the 13th inst. on the subject of the Midwives Registration Bill of last session, and in reply I am directed by his Grace to state for the information of the General Medical Council that there would appear to be no necessity for the Council to consider the provisions of the Bill until it is re-introduced."

Sir RICHARD THORNE moved that the Council adopt the report and appoint the present Committee to report upon any Midwives Registration Bill which might be submitted to the Council by the Lord President before or during the present session of Parliament.

Dr. GLOVER seconded this motion.

Mr. HORSLEY said that he thought the functions of the Council in this connexion were to do something more than merely alter Bills sent down by the Privy Council, and he thought the letter of Sir Charles Lennox Peel showed that the Privy Council expected something more. He would suggest that the Committee be appointed to watch the progress of the Midwives question.

Sir RICHARD THORNE said he did not think it would be possible for such a Committee as this, composed of members from all parts of the kingdom, to watch the progress of the question.

Mr. HORSLEY pointed out that watching committees were frequently appointed by other bodies when legislation was in active progress or was threatened. Upon this subject they were threatened with legislation, and it might be necessary for this Council not merely to report upon any given Bill but to tell the Privy Council how far any legislation on

Digitized by Google

the subject interfered with the existing Medical Acts. He moved in accordance with his suggestion.

Dr. BRUCE seconded the motion.

Mr. BROWN expressed the opinion that the motion of Sir Richard Thorne would meet the whole case.

Mr. CARTER said it would be a wholly new departure for this Council to take anything that could be looked upon as an initiative step with regard to midwifery. They had never regarded the question as falling within the proper limits of their activity except in so far as they had responded to an appeal made to them by the Government for their opinion as a medical body upon particular propositions. It was not for the Committee to discuss general questions, because these would afterwards have to be discussed by the whole Council if they were discussed at all.

After some further discussion Mr. Horsley withdrew his motion, and the motion of Sir RICHARD THORNE was agreed to.

On the motion of Mr. BROWN, seconded by Dr. GLOVER, the name of Mr. Horsley was added to the list of the Committee to take the place of Dr. Rentoul.

Dr. MCVAIL then moved:—

That the General Medical Council is of opinion that the practice of midwifery cannot be safely entrusted to persons who have a less knowledge of midwifery and of medicine and surgery than is required for admission to the Medical Register.

This, he said, was in his opinion a fitting opportunity for the Council to give a clear expression of opinion upon this question which had been exciting so much attention. To do so would be of very considerable assistance to the Government and to any Members of Parliament who might be induced to introduce a new Bill, and it would lighten the labours and clear the way of the Committee of the Council on the subject.

Dr. GLOVER, rising to a point of order, asked whether such a motion as this, inconsistent as it was with the resolutions of the Council, was in order.

The CHAIRMAN replied that he was not prepared to rule the motion out of order.

Dr. MCVAIL continuing said that the main point he wished to emphasise was that the intention of those who were promoting this legislation was to create a new class of practitioners, a class of persons who would independently conduct midwifery cases. Both Bills applied to women only, but it was perfectly certain that the matter would not rest there. There were throughout the country a great many men who had gone through a part of the medical curriculum and who had been attending cases of midwifery for a long time. This Council had been endeavouring to put down this class and were they now to open a door for them? Were they to say to men of that kind that while they were not fit to enter the profession they could go and join this inferior class of practitioners even though they happened to be men. If they said they were not to do that then they were going to exclude from this grade the very people who were of all others the most competent to meet the requirements of the situation—men who had got a certain amount of surgical and medical training and who had had great experience in midwifery cases. Not only so, but practitioners so admitted, whether men or women, would unquestionably seek to extend the bounds of their work and would begin to treat the diseases of women and of children. They would gradually come to be practitioners upon whom the mothers in the poorer classes of society would depend for advice in connexion with themselves or their offspring. Severe tests were now imposed upon dentists, but would anybody contend that the responsibility of a dentist was to be compared with that of a person who attended a case of midwifery. In all these proposals women were to be entitled to attend cases without the supervision of a medical man. When one of the Bills was being discussed by this Council he proposed that there should be an amendment to provide for the supervision of a medical practitioner, but the proposal was rejected. The statement was made that every year in England and Wales 500,000 women were attended by midwives, but was that to cause this Council to completely disunite the three great medical sciences which were united for them finally in the Act of 1886? Could this great country not meet the wants of these 500,000 women by securing for them through the means of the various boards of guardians and parochial boards the attendance of registered medical practitioners? The profession, they were told—and no journal told them more persistently than THE LANCET—was becoming overcrowded. If that were so, then surely the profession could undertake this extra work, and he thought there could be no higher duty for the Government than to give assistance to women in these circumstances. He did not object to a system of registration for midwifery nurses, but he objected to the creation of a body of practitioners who would without medical supervision undertake the management of midwifery cases and rely upon their judgment alone for their treatment. It might be said that what he proposed would be unfair to women but he would remind the Council that women were now admitted to the medical profession practically on the same terms as men. If women desired to follow midwifery as a profession they could enter the profession in the ordinary way.

The CHAIRMAN said he would suggest that the Council should not go into the question of midwives against midwifery nurses or women medical practitioners. He thought they should confine themselves to the discussion of the general question which was raised by Dr. McVail's motion.

Dr. ATTHILL in seconding the motion said that no one who had had such extensive practice as he had had in midwifery cases could fail to be impressed with the ills which were inflicted upon women and children by want of knowledge of the principles and practice of midwifery, and every effort should be made by this Council to enforce a proper standard of education in midwifery upon every person who went upon the Register. It was impossible to teach midwifery in three or six months as some of these institutions professed to do, and the sooner the Council looked into the matter the better. He urged for the sake of humanity that the Council would not vote against this abstract resolution.

Mr. CARTER said he doubted very much whether the Council would act wisely by adopting this resolution. One would think that Dr. McVail had been speaking of something new. Instead of that he had been speaking of a practice as old as human nature itself. What they had to deal with in this Council were the facts of life as they found them, and if the Council could not remove the evils incidental to the employment of women in midwifery cases they should do their best to minimise them, and he thought that they should probably find that minimising these evils by giving instruction to women would be a step towards doing away with them entirely, and towards producing in the public mind a demand for a better educated class of practitioners still.

Dr. GLOVER said he could not help thinking that this resolution was inconsistent with the previous action of the Council. He assured Dr. McVail that the Bills only contemplated women practising midwifery under the most limited circumstances and with the supervision of the medical profession. He was as anxious as Dr. McVail that there should be supervision, and he would tell the Council that at a most agreeable though small meeting of the Committee on the Midwives Bill, consisting of Mr. Brown, Dr. Rentoul, and himself, after much difference of opinion they agreed upon a clause providing that in every case attended by a midwifery nurse in which the labour was unusually prolonged or difficult or in the after period of which there was anything unsatisfactory in the health of the mother or child the midwifery nurse should send without delay for one of such registered men as should be appointed for such purpose by the local sanitary authority. Dr. McVail said that the curriculum of these women would be short and the examination worth nothing at all. But a very small amount of training was a very great additional security for the patient, and this was amply proved by the statistics of maternity institutions. As to men being included in the scope of this legislation, he did not believe that any Parliament would sanction anything of the kind, and, moreover, the present Medical Acts forbade it. Midwives they had with them now as they had always had them, and the object of this legislation was to bring them under control and limit their numbers. As to the 500,000 women attended by midwives Dr. McVail proposed to make them all paupers, a thing which would never be tolerated. He hoped the Council would not adopt this resolution, which he insisted would destroy the influence of the Council, and the profession in controlling this legislation. If this resolution were passed it would take the matter entirely out of the hands of the Council and of the profession. According to any practical proposals this Council was to sanction the rules that

Digitized by Google

were to be provided and these rules were to be administered by a body consisting almost wholly of medical men. This resolution would stultify the Council and contradict its previous resolutions, and would be a hint to the Government that in this matter they should not seek the advice of the Council.

Dr. MACALISTER, seconded by Mr. BRYANT, moved as an amendment:—

That it is inexpedient for the Council to commit itself to an abstract resolution which may preclude it from giving full consideration to any future Midwives Registration Bill submitted to it by the Government.

Dr. ATTHILL said that in all the circumstances he thought this amendment was very judicious.

A reply from Dr. MOVAIL having been heard, the vote was taken, when Dr. MacAlister's amendment was carried by 16 votes to 6.

The amendment was then put as a substantive motion.

Mr. BROWN said he wished to take the opportunity of explaining his position with regard to the clause referred to by Dr. Glover. He only agreed to the clause by way of minimising the manifest evils of the Bill, and he reserved to himself the right to prepare a minority report to the effect that no legislation of this kind was necessary.

The amendment was carried as a substantive motion and became the finding of the Council.

Fines under the Medical Acts.

The following report on this subject by the special committee was read, viz.:—

Dr. Glover, as the chairman of this Committee, informs the General Council that in the course of the last session he had a second interview with Mr. Jessie Collings on the subject of penalties under the "Medical Acts and the Metropolitan Police Courts Bill," and at his request on this subject, in the course of which he expressed to Mr. Collings the anxious wish of the Council that fines imposed under the Medical Acts should be paid over in accordance with the spirit and letter of the Medical Acts to the treasurers of the Medical Council, and in defrayment of the expenses of prosecutions, Mr. Collings expressed much sympathy with the object of the Medical Council, and willingness to consider it on any suitable occasion: but said that the present measure was so technical and limited in its nature that the subject could not be dealt with in it.

The report was entered on the minutes, and it was agreed to re-appoint the committee with the addition of Mr. Horsley.

The Council then adjourned.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON. — In November the following candidates passed in the undermentioned subjects:—

Surgery.—J. Cater, King's College Hospital; and F. H. Fawcett Middlesex Hospital.
Medicine.—L. Blkind, Berlin; and W. A. B. Smith, King's College Hospital.
Forensic Medicine.—J. Ash, St. Thomas's Hospital; and T. H. Bailey and S. R. Bhagtani, King's College Hospital.
Midwifery.—F. G. Aldrich, Charing-cross Hospital; T. H. Bailey, King's College Hospital; F. W. Chesnaye, St. George's Hospital; F. R. Greenwood, St. Bartholomew's Hospital; B. S. Mankar, London Hospital; H. H. Monckton, King's College Hospital; and A. W. Shea, Sheffield and Dublin.

The diploma of the Society was granted to the following candidates, entitling them to practise Medicine, Surgery, and Midwifery: Messrs. J. Cater, S. R. Bhagtani, F. R. Greenwood, B. S. Mankar, H. H. Monckton, and A. W. Shea.

ROYAL COLLEGE OF SURGEONS IN IRELAND: FELLOWSHIP EXAMINATION. — The following gentleman having passed the necessary examination has been admitted a Fellow of the College:—

D. P. O'Brien, L.R.C.S. Irel., &c.

The following gentlemen have passed the Primary part of the examination for the Fellowship:—

R. Allen, B.Ch., &c., R.U.I.; W. J. Corbett, L.R.C.S. Irel., &c.; J. M. Redington, L.R.C.S. Irel., &c.; Alfred H. Jacob, C. B. Pasley, and H. F. Stapleton.

ASSAULT ON A WORKHOUSE MEDICAL OFFICER.—On Nov. 15th a male pauper was sentenced to a month's hard labour by the magistrate at the Lawford's Gate, Bristol, Police Court for an assault upon Mr. R. Norgate, L.R.C.P. Lond., M.R.C.S. Eng., the resident medical officer of the Stapleton Workhouse. Evidence showed that the prisoner had struck Mr. Norgate in the face and had torn his clothes.

GREAT NORTHERN CENTRAL HOSPITAL.—Arrangements are being made for endowing a bed in the Great Northern Central Hospital in memory of the Duchess of Teck. A donation of £100 towards this object has been offered by Mr. C. F. Cory-Wright. A further sum of £850 is required, contributions to which will be received either by the President (the Baroness Burdett-Coutts) or by the honorary secretary of the Ladies' Association at the hospital.

BANQUET TO PROFESSOR ALFRED HUGHES AT CARDIFF.—On Nov. 20th last Professor Alfred Hughes, of King's College, London, was entertained at the Angel Hotel, Cardiff, at a complimentary banquet given conjointly by the Council and Senate of the University College, Cardiff, and the members of the Cardiff Medical Society. The chair was taken by Mr. Treharne in the absence of Principal Viriamu Jones. In proposing the toast of the evening the chairman referred to the general regret felt at the departure of Professor Hughes from the chair of anatomy in Cardiff and recalled the good and honest work he had done in the early years of the new medical school and also his universal popularity among the students as their teacher and friend, wishing him prosperity in his new sphere in London. Professor Hughes, in his reply, congratulated the council of the College on the appointment of Professor Dixon as his successor and warmly eulogised his distinctions as a teacher and investigator. In dealing with the future prospects of the medical school Professor Hughes maintained that the success which the school had achieved and the rapid developments of the clinical resources of the district justified them in looking forward at no great distant date to the further development of the school by providing lectures on the final subjects of the curriculum; if that were done he suggested that the authorities of the University of Wales might well take steps as to acquiring powers of granting degrees in medicine.

APOTHECARIES' HALL OF IRELAND.—At a meeting of the Governor and Court of the Apothecaries' Hall of Ireland the following gentlemen were appointed examiners to conduct the examinations in Medicine, Surgery, and Midwifery:—Chemistry and Physics: E. Davy, M.B., Dub., Government Analyst; N. Hartley, F.R.S., F.I.C., Professor of Chemistry, College of Science, Ireland; C. R. Tichborne, F.I.C., Diplomate Public Health R.C.S. Irel., L.A.H., Ex-examiner Chemistry (Dub. Univ.). Pharmacy: W. V. Furlong, L.R.C.P. Edin., L.R.C.S. Irel., L.A.H.; G. A. Stritch, L.F.P.S. Glasg., L.A.H. Anatomy: A. Birmingham, M.D. R.U.I., F.R.C.S. Irel., Professor of Anatomy, Catholic University, Fellow and Examiner, R.U.I.; (vacant). Biology: A. J. Blaney, M.B., B.Ch., Examiner Biology, R.U.I.; J. A. Johns, M.B., B.Ch. Dub., L.A.H. Materia Medica: John Evans, L.R.C.S. Irel., L.A.H., Ex-examiner, P.S.I.; S. M. Thompson, L.R.C.P. Irel., L.R.C.S. Irel., L.A.H., Visiting Physician to South Dublin Union. Physiology: D. J. Coffey, M.B., B.Ch. R.U.I., Lecturer on Physiology, Cecilia-street Medical School; G. B. White, M.B. Dub., F.R.C.S. Irel., L.A.H., Examiner R.C.S. Irel. Hygiene: D. E. Flinn, F.R.C.S. Irel., Diplomate Public Health, R.C.S. Irel.; A. Roche, M.R.C.P. Irel., L.R.C.S. Irel., Examiner Hygiene, R.U.I. Medical Jurisprudence: H. A. Auchinleck, F.R.C.S. Irel., L.R.C.P. Edin., L.A.H., Professor of Medical Jurisprudence, R.C.S. Irel.; J. E. Kenny, L.R.C.P., L.R.C.S. Edin., Coroner City of Dublin. Pathology: E. J. McWeeney, M.D., M Ch. R.U.I., Examiner in Pathology, Pathologist to Mater Misericordiæ and Coombe Hospitals; C. M. O'Brien, M.B. Durh., L.R.C.P., L.R.C.S. Irel., L.A.H., Ex-Senior Resident Surgeon and Registrar Jervis-street Hospital, Dublin, late acting Clinical to Out-Patients Middlesex Hospital, London. Midwifery and Gynæcology: T. More Madden, M.D. (Hon. Causâ) R.U.I., F.R.C.S. Edin., Obstetric Physician, Mater Misericordiæ Hospital, Ex-Assistant Physician, Rotunda Hospital; R. D. Purefoy, M.B. Dub., F.R.C.S. Irel., L.A.H., Master, Rotunda Hospital. Ophthalmology: A. H. Benson, M.B. Dub., F.R.C.S. Irel., Ophthalmic and Aural Surgeon to the City of Dublin and St. Mark's Hospital; R. J. Montgomery, M.B. Dub., F.R.C.S. Irel., L.A.H., Assistant Surgeon to St. Mark's Hospital, Ophthalmic Surgeon to Drumcondra Hospital. Surgery (appointed by the General Medical Council): A. Chance, F.R.C.S. Irel., L.A.H., Surgeon to Mater Misericordiæ Hospital; H. A. Thompson, M.D., B.Sc. Edin., F.R.C.S. Edin. Medicine: W. E. Ashley Cummins, M.D., M.Ch. R.U.I., L.A.H., Professor of Practice of Medicine, Queen's College,

Digitized by Google

Cork, Senior Physician Cork County and City Hospital for Women and Children, &c.; and J. B. Coleman, M.D.R.U.I., Physician to Richmond, Whitworth, and Hardwicke Hospital.

SIR JOHN LUBBOCK has consented to deliver the first sessional lecture of the Royal British Nurses' Association on Wednesday, Dec. 1st. The lecture will be given in the rooms of the Zoological Society, 3, Hanover-square, W., at 8 P.M., on the subject "Ants." A limited number of seats will be available for the public.

FREEMASONRY.—*The Sancta Maria Lodge.*—The following are the officers of the new Lodge the inauguration of which we announced last week:—His Royal Highness the Prince of Wales, Worshipful Master; W. Bro. Edmund Owen, M.B. Lond., F.R.C.S. Eng., Deputy Master; W. Bro. Alexander Stewart Brown, F.R.C.S. Edin., Acting I.P.M.; Bro. the Hon. Reginald Bootle Wilbraham, Senior Warden; W. Bro. J. Ernest Lane, F.R.C.S. Eng., Junior Warden; W. Bro. the Rev. H. S. Cronin, M.A., Chaplain; W. Bro. Malcolm Morris, F.R.C.S. Edin., Treasurer; W. Bro. M. Handfield-Jones, M.D. Lond., Secretary; W. Bro. A. P. Luff, M.D. Lond., Senior Deacon; W. Bro. Henry Pearce, M.R.C.S. Eng., Junior Deacon; Bro. P. P. Whitcombe, M.B. Lond., Inner Guard; W. Bro. E. A. Priddle, B.A., Director of Ceremonies; Bro. M. Mitchell Bird, M.D. Durh., Steward; W. Bro. C. D. Leyden, Steward; and Bro. W. J. Gow, M.D. Lond., Steward. A large number of names have been proposed as initiates, amongst which may be mentioned that of the Dean of the Medical School of St. Mary's, Mr. G. P. Field. The deputy master will have a busy time during the coming twelve months as the names of many students as well as of several of their teachers have been given in as intending adherents.

RUSSIAN IMPRESSIONS OF THE PLAGUE IN BOMBAY.—At a largely attended meeting of the Kief Medical Society Professor Vuisokóvitch recently gave an account of his expedition to Bombay to study the outbreak of plague. The Russian Commission of which he was the head had made a careful study of the epidemic from the clinical, bacteriological, and other aspects, and the general impression they had gathered was that although plague is a very severe disease yet it is easier to deal with and control than some other diseases such as diphtheria or cholera. The plague bacillus dies quickly if completely dried up and it cannot live long in water. The disease is spread from man to man directly or by the medium of fomites; it is in fact a purely "house-disease." The part played by rats in spreading it is still doubtful. The most successful measures against the spread of the epidemic have been the following: the searching out of cases; their segregation in hospitals; removal of the healthy from an infected house; disinfection of the house and contents; examination of persons arriving at, or departing from, any district; and an eight or ten days' quarantine. Unfortunately these measures met with resistance in an unenlightened community; consequently it is of more importance to endeavour to keep the infection out of a country or district. This is not difficult if proper precautions are taken on the frontier. Professor Vuisokóvitch stated that neither Yersin's nor Khafkin's prophylactic inoculations had proved to be quite satisfactory. In monkeys neither gave more than ten or fourteen days' immunity. The best results followed the injection of a fresh agar cultivation, killed by heating to 60° C. for one hour. Yersin's serum had given very encouraging results as a curative agent. Among 150 patients so treated the mortality had, it is true, been 40 per cent., but it would probably have been less could many of the patients have been seen at an earlier stage of the disease.

Appointments.

Successful Applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

BREW, C., M.B., B Ch. Dubl., has been appointed a Medical Officer for Bray Dispensary.

CLOUGH, JOSEPH, L.R.C.P. Lond., M.R.C.S., has been appointed a Medical Officer for the No. 1 Sanitary District of the Hunslet Township, vice A. Nicholson, resigned.

DICKSON, J. D., M.D. Irel., M.Ch., L.R.C.S. Irel., has been re-appointed Medical Officer of Health by the Marlow Urban District Council.

HODGE, S. R., M.R.C.S., L.R.C.P. Edin., has been appointed a Clinical Assistant to Out-patients at the Chelsea Hospital for Women.

HOOLE, H., M.D. Lond., M.R.C.S., has been appointed Chief Medical Examiner in Great Britain and Ireland for the National Mutual Life Association of Australasia.

JACOB, E. L., M.R.C.S., has been re-appointed Medical Officer by the Walton Urban District Council.

JOHNSTONE, J. L., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health by the Orrell Urban District Council.

MACDONALD, J., M.B., C.M. Edin., has been appointed Medical Officer for the Forbes Dispensary, Inverness, vice G. A. Lang.

MARR, GEORGE, M.B., C.M., has been appointed a Clinical Assistant to Out-patients at the Chelsea Hospital for Women.

MASON, F. W., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed a Medical Officer for the Nos. 1 and 5 Sanitary Districts of the York Union.

MILLIGAN, H. N. D., M.B., C.M. Edin., has been appointed a Member of the Medical Staff of the Linen and Woollen Drapers' Institution.

MORRIS, CYRIL G., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Fourth District of the Bath Union, vice F. W. Hanham, resigned.

MURRAY, WM., M.A., M.B., C.M. Aberd., has been appointed Resident Surgeon at the Birmingham General Dispensary.

NABARRO, D. N., B.Sc., L.R.C.P., M.R.C.S., has been appointed a House Physician, University College Hospital.

SHARPE, S. H., M.B., B.S. Dubl., has been appointed Senior Resident Surgeon to the Jervis-street Hospital, Dublin.

SLOCOCK, RICHARD, B.A. Oxon, M.R.C.S., L.R.C.P., has been appointed House Surgeon at the Royal Portsmouth Hospital.

STEVENS, A. E., M.B. Durh., M.R.C.S., L.R.C.P., has been appointed by the Indian Government for Special Plague Duty in Bombay.

STREET, A. Ernest, L.R.C.P. Lond., M.R.C.S., has been appointed Second Assistant Medical Officer for the Lewisham Union Infirmary.

WHYTE, G. F., M.B., C.M. Edin., has been appointed a Resident Medical Officer for the Dundee Sick Poor Hospital.

WILKINSON, J. HOWARD, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health for the County Borough of Dudley.

WADE, R., M.R.C.S., has been appointed Medical Officer of Health for the Highbridge Urban Sanitary District.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ADDENBROOKE'S HOSPITAL, Cambridge.—Resident Assistant House Surgeon. Board, lodging, and washing provided in the hospital. No salary.

BRECKNOCK COUNTY AND BOROUGH INFIRMARY.—Resident House Surgeon, unmarried. Salary £70 per annum, with furnished apartments, board, attendance, fire, and gas. Applications to the Secretary, 6, Bulwark, Brecon, South Wales.

BRIGHTON AND HOVE LYING-IN INSTITUTION AND HOSPITAL FOR WOMEN, West-street, Brighton.—House Surgeon, unmarried. Salary £80 per annum, with furnished apartments, board, gas, coals, and attendance.

BRIGHTON THROAT AND EAR HOSPITAL, Queen's-road, Brighton.—Non-resident House Surgeon. Salary at the rate of £52 per annum.

CARDIFF INFIRMARY.—Assistant House Surgeon for six months. Board, washing, and apartments provided.

DERBYSHIRE ROYAL INFIRMARY.—Resident House Surgeon and a Resident House Physician for twelve months. Salary of House Surgeon £100 per annum and of House Physician £80 per annum, with apartments and board in both cases.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Glamis-road, Shadwell, E.—House Physician for six months. Board, residence, &c., provided, and an honorarium of £15 15s. granted conditionally.

HEREFORD GENERAL INFIRMARY.—Resident House Surgeon, unmarried. Salary £100 per annum, with furnished rooms, board, washing, gas, coals, and attendance.

LIVERPOOL DISPENSARIES.—Head Surgeon. Salary £200 per annum. Also an Assistant Surgeon. £80 for the first year and £90 afterwards, with apartments, board, and attendance in each case. Both must be unmarried. Applications to the Secretary, 31, Moorfields, Liverpool.

PARISH OF ROUSAY AND EGILSHAY, Orkney.—Resident Medical Officer. Salary £51 sterling per annum. Apply to the Clerk of the Parish Council, Rousay, Orkney.

PARISH OF ST. GILES, CAMBERWELL.—Assistant Medical Officer for the Infirmary, at Havill-street, Camberwell, and the Workhouse at Gordon-road, Peckham, also for Relief Duty at the Constance-road Workhouse of the Parish, for one year. Salary £50, with apartments board, and washing. Applications to the Clerk to the Guardians, Guardians' Offices, 29, Peckham-road, S.E.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, London.—Assistant Resident Medical Officer for four months. Salary at the rate of £50 per annum, with board, residence, and washing.

ROYAL BERKS HOSPITAL, Reading.—House Physician for six months. Salary £60 per annum, with board, lodging, and washing. Also Assistant Medical Officer for six months. Board, lodging, and washing provided, and an honorarium of 10 guineas awarded conditionally.

ROYAL LONDON OPHTHALMIC HOSPITAL, Moorfields, E.C.—Non-resident Assistant House Surgeon to Out-patient Department. Salary £75 a year.

SALISBURY INFIRMARY.—Assistant House Surgeon for six months, unmarried. Board, lodging, and washing provided, and an honorarium of £10 given conditionally.

ST. THOMAS'S HOSPITAL, Albert Embankment, Westminster-bridge, S.E.—Assistant House Physician.

STROUD GENERAL HOSPITAL.—House Surgeon. Salary £80 per annum, with board, lodging, and washing.

UNIVERSITY COLLEGE, Liverpool.—Senior Demonstrator of Physiology. Salary £125.

VICTORIA HOSPITAL FOR CHILDREN, Queen's-road, Chelsea, S.W.—Dental Surgeon.

WALLASEY DISPENSARY.—House Surgeon, unmarried. Salary £150 per year, with furnished house, coal, and gas.—Applications to Mr. W. Heap, Elm Mount, Penkett-road, Liscard, Cheshire.

WIRRAL CHILDREN'S HOSPITAL, Woodchurch-road, Birkenhead.—House Surgeon. Salary £50 per annum, with board, apartments, and laundry. Applications to the Honorary Secretary, 5, Bamford-place, Liverpool.

YORKSHIRE COLLEGE, LEEDS.—Joint Lecturer on Forensic Medicine in the Medical Department.

Births, Marriages, and Deaths.

BIRTHS.

BARTON.—On Nov. 24th, at Sunnyside, Wimbledon, the wife of P. Fred. Barton, B.A., M.R.C.S., L.R.C.P., of a daughter.

ELLERTON.—On Nov. 20th, at Priory-terrace, Leamington, the wife of J. F. Heise Ellerton, M.D., of a daughter.

FREELAND.—On Nov. 17th, at Beaumont-street, Portland-place, the wife of H. Harding Freeland, L.R.C.P. Lond., M.R.C.S., of a son.

HORNER.—On Nov. 22nd, at St. Mary's-road, Walthamstow, the wife of Charles J. Horner, L.R.C.P. Lond., M.R.C.S., of a son.

LUCE.—On Nov. 18th, at Burton-road, Derby, the wife of Richard H Luce, M.B., F.R.C.S., of a daughter.

LUFF.—On Nov. 18th, at 31, Weymouth-street, W., the wife of Arthur P. Luff, M.D, F.R.C.P., of a daughter.

TAYLOR.—On Nov. 17th, at Boscombe, Hants, the wife of James Taylor, M.D., of a son.

MARRIAGES.

PHILIP—PONDER.—On Nov. 23rd, at St. Mary's Church, Kippington Sevenoaks, Andrew Philip, M.B., of Newport, Fife, to Alice Marion, eldest daughter of J. Edwin Ponder, of Sevenoaks, Kent.

WICKHAM—GILLING.—On Nov. 17th, at St. Peter's Church, Bournemouth, Gilbert Henry Wickham, M.B., second son of the Rev. H. J. Wickham, of Winchester, to Emma, daughter of the late John Gilling, of Linkfield Court, Bournemouth, and Redhill, Surrey.

DEATHS.

CARTER.—On Nov. 19th, at Hastings, Charles Henry Carter, F.R.C.S. aged 80 years.

HEDDLE.—On Nov. 19th, at St. Leonards, St. Andrews, M. Forster, Heddle, M.D., F.R.S.E., Emeritus Professor of Chemistry in the University of St. Andrews.

HORSFALL.—On Nov. 23rd, at Masham, Yorks, Henry Horsfall, M.D. St. And., aged 64 years.

WYMAN.—On Nov. 21st, at Red Brae, Putney-hill, Cuthbert Wyman, M.A., M.D., B.C. Cantab., F.R.C.S. Eng., L.R.C.P., in his 32nd year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (29th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.).

TUESDAY (30th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).

WEDNESDAY (1st).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.).

THURSDAY (2nd).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.).

FRIDAY (3rd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.).

SATURDAY (4th).—Royal Free (9 A.M. and 2 P.M.), Middlesex, (1.30 P.M.), St. Thomas's (3.30 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

WEDNESDAY (1st).—BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M. Papers:—Dr. J. A. Shaw-Mackenzie: The Treatment of Syphilis by External Methods.—Dr. H. Solly (Harrogate): The Treatment of Syphilis at Harrogate.

OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown by Dr. Macnaughton Jones, Mr. Dauber, Dr Boxall, Dr. J. Phillips, Dr. Lea, Dr. McCann, and others. Papers:—Dr. Tate: Three Cases of Pyometra complicating Cancer of the Cervix Uteri.—Dr. McKerron: The Obstruction of Labour by Ovarian Tumours in the Pelvis.

THURSDAY (2nd).—HARVEIAN SOCIETY.—Mr. Juler: The Syphilitic Diseases of the Eye and its Appendages. (Harveian Lecture.)

FRIDAY (3rd).—WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, W.).—8.30 P.M. Clinical Evening. Dr. F. H. Low: A Series of Skiagrams illustrating the Location of Foreign Bodies.—Dr. J. B. Ball: A Case of Acromegaly.—Dr. S. Taylor: Three Cases of Symmetrical Nodes of Radii in Women.—Mr. Keetley: Two Cases of Stricture of the Œsophagus and of the Pylorus in the same Patient.—Mr. Bidwell: Note on a Case of Chancre of the Cheek.—Mr. McA. Eccles: Two Cases of Depressed Fracture of the Skull treated by Trephining.

LECTURES, ADDRESSES, DEMONSTRATIONS, ETC.

MONDAY (29th).—LONDON POST-GRADUATE COURSE.—London Throat Hospital, Gt. Portland-st., W., 8 P.M., Dr. H. Law: Demonstration of Cases.

TUESDAY (30th).—LONDON POST-GRADUATE COURSE.—Bethlem Hospital, 2 P.M., Dr. Craig: Moral and Impulsive Insanities.—Hospital for Skin Diseases, Blackfriars, 4.30 P.M., Dr. Abraham: Leprosy.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3.30 P.M. Mr. Victor Horsley: Surgery of the Nervous System.

HOSPITAL FOR NERVOUS DISEASES (73, Welbeck-street).—4.30 P.M. Dr. T. D. Savill: On Disorders of the Nervous System characterised by Muscular Tremor, with cases.

WEDNESDAY (1st).—LONDON POST-GRADUATE COURSE.—Parkes Museum, Margaret-st., W., 4.30 P.M., Prof. A. Wynter Blyth: Disinfection and Disinfectants.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. Acland: Data for forming a Prognosis in Pulmonary Tuberculosis, illustrated by Cases.

EVELINA HOSPITAL (Southwark-bridge-road, S.E.).—4.30 P.M. Mr. F. C. Abbott: The Surgery of Rickets. (Post-Graduate Course.)

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Dr. Ball; Throat Cases.

THURSDAY (2nd).—LONDON POST-GRADUATE COURSE.—Central London Sick Asylum, Cleveland-st., W., 5.30 P.M., Mr. J. Hopkins: Clinical Lecture.

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Dr. Barlow.

FRIDAY (3rd).—LONDON POST-GRADUATE COURSE.—King's College, 5 to 6 P.M., Prof. Crookshank: Tetanus, Rabies, and Cholera.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

CHINOSOL FOR THE ANTISEPTIC TREATMENT OF TUBERCULOSIS.

OF late years the value of the administration of antiseptics in some cases of tuberculosis has been generally acknowledged; the antiseptics which have hitherto been chiefly employed have been creosote and guaiacol. In the *Allgemeine Medicinische Central-Zeitung*, No. 75, 1897, Dr. A. G. Cipriani has given an account of some cases of tuberculosis in which he has employed chinosol. This substance has been known for some time as a non-irritating and comparatively non-poisonous antiseptic, but we believe it has not been employed previously for tuberculosis. Dr. Cipriani gives notes of eight cases which he has treated, three of the cases being examples of tuberculous glands; in two cases there was tuberculous caries of bone; and in three cases the tuberculosis had attacked the lungs; in these three cases the chinosol was given by the mouth, but in the others the drug was injected locally in the form of a watery solution. When administered by the mouth one gramme was given during the day in divided doses, and it seems to have been well borne. In all the cases rapid and apparently permanent improvement followed the treatment. The number of cases is too small to justify any opinion being formed as to the real value of the drug, but since chinosol appears to be harmless, even in somewhat large doses, the treatment certainly deserves a more extended trial.

Edina informs us that he knows of a case where an American university has conferred the degree of Doctor of Medicine on a layman who had merely presented a thesis. He asks our opinion of the "degree" and of the "university." The institution has either been itself imposed upon or it is a bogus university—a degree shop—of which there once were many in the States. We do not know the place by name.

A MISTAKEN DIAGNOSIS UNDER DIFFICULT CIRCUMSTANCES.

A FRENCH medical journal mentions a case which shows how seriously a medical man may occasionally be blamed for the consequences of a diagnosis which, made under most unfavourable circumstances, may ultimately be shown to have been mistaken. A workman fell into a kneading-machine, and when he was extricated was found to be covered with wounds and to have sustained several fractures, amongst others the surgeon who attended him made out one of the neck of the femur. The man was unconscious for a fortnight, but after a couple of months' careful and assiduous attention the medical man had the satisfaction of being able to allow his patient to get up. The fractured femur, however, was shortened considerably. The man being insured against accidents, the company sent its own medical adviser to see the case, and he reported that the neck of the femur had not been fractured but that there was an unreduced dislocation of the hip. The company, not recognising the great difficulty of diagnosing and treating such a complicated case, have put in a claim against the medical man for 80,000 francs and the patient has added a claim for 10,000 francs compensation. What view the French law-courts will take of the matter remains to be seen.

R. P.—We do not recommend individual practitioners. The matter is one upon which the family medical man can best advise. If he or the patient's friends require a second opinion he will know the most suitable consultant.

WANTED SUGGESTIONS FOR TREATING A GANGRENOUS ULCER.

To the Editors of THE LANCET.

SIRS,—If you will insert the following notes in THE LANCET you will confer on me a great favour. Some six weeks ago I was consulted by a man who had received a slight injury on the front of one of his tibiæ which caused a small sore. He went to a druggist, who gave him a mixture of nitrate of silver and water, this solution was to be painted on the sore night and morning. After doing so for three weeks the patient applied a poultice and removed the scab, leaving a deep ulcer two inches in diameter. The case then came under my care. The upper two-thirds of the ulcer quickly healed, but the lower third gradually spread and encroached on the healthy skin, at the rate of about an eighth of an inch per diem. The patient is a most docile one and carries out all instructions most assiduously. So far my treatment has not improved the local condition, and I should very much like to have advice from some of the readers of THE LANCET.

I am, Sirs, yours faithfully,

Belmont Lodge, New Eltham, S.E., Nov. 23rd, 1897. JOHN D. RICE.

A RASH OPERATOR PUNISHED.

A CASE which for some time past has been much discussed locally, as well as throughout the whole medical profession in France, was recently decided in the Pau Court of Appeal. The circumstances were briefly as follows. A young medical practitioner named Lassalette, residing in the town of Pau, and who had qualified only about eighteen months previously, having been called in to attend a woman who was complaining of an abdominal tumour undertook to perform one of the most serious operations in modern surgery—namely, total hysterectomy, in spite of the fact that a distinguished surgeon of Bordeaux had given it as his opinion that active intervention was contra-indicated. It should, however, be noted that the consultant's views were based on an error in his diagnosis, for he believed that the patient was suffering from a mobile cyst, whereas in reality the affection was a very large fibroma. On the day fixed for the operation the young surgeon, accompanied by a medical man younger than himself and his own chamber-maid as his sole assistants, proceeded to the woman's lodgings, which were on the ground floor of a many-storeyed building. The chamber-maid having administered chloroform the patient, as soon as she was completely anæsthetised, was carried up to one of the landing places and placed upon an ordinary kitchen table. The operation is said to have lasted two hours, but although apparently successful the patient died suddenly during the night. An official inquiry was at once instituted, and at the necropsy, which was duly conducted by experts, two faults of major gravity were disclosed. A forgotten artery forceps was found inside the abdomen and also the unsecured stump of an artery, the bleeding from which had been the immediate cause of death. Upon this evidence the operating surgeon was condemned to two months' imprisonment and a fine of 500 francs; but dissatisfied with the sentence, and apparently refusing to admit that he was in the slightest degree blameworthy, he lodged an appeal. The result of this ill-advised procedure has now been declared. The presiding judge being of opinion that there was total absence of all extenuating circumstances increased the first pronounced imprisonment by a month and confirmed the fine.

PURE TOBACCO.

THE remarks which we have had occasion to make more than once in this journal as to the desirability of tobacco being pure and free from artificial flavouring or scents have created some interest in this matter and not the least amongst the trade. It may be noticed with satisfaction that some members of the tobacco trade are honest enough to admit that inferior tobacco is often scented, a practice which even they regret as bringing tobacco into discredit. "It is a mistake," says one in a communication to us, "this flavouring; it is educating smokers falsely and spoiling their palate." "If a tobacco is good," he adds, "there is no need of any added flavouring." This coming from a member of the trade is an interesting endorsement of our views. We have also received various specimens of tobacco to illustrate what unsophisticated tobacco is. Mr. Thomas R. Seymour, of 4, North-street, Bristol, encloses us some tobacco for the pipe about the purity of which there can be little doubt, and it is far preferable to the stuff which reeks of Tonquin bean or other equally objectionable scent. Again, Messrs. Oakes and Co., of 46, New Broad-street, have sent us specimens of their "Little Indians" cigarettes which are all tobacco, the wrapper being tobacco and not paper. The combustion of paper materially spoils the flavour of good tobacco, but when the wrapper is tobacco this is avoided. The cigarettes are mild-smoking, of agreeable flavour, and free from acridity.

Sol.—If the false rumour is public it is right that the correction should be made publicly.

"THE PARISH NURSE DIFFICULTY."

To the Editors of THE LANCET.

SIRS,—The article written by me to which you refer in an annotation in THE LANCET of Nov. 20th was written with a purpose—i.e., to draw attention to the fact that villagers cannot get nurses, that the present system of charity nurses is a failing in that if any of the chief subscribers die or leave the nurse has to be given up. Secondly, she is generally placed under a committee yet is responsible to no one. Thirdly, not being fully qualified is frequently found a drawback, as in country places the medical practitioner often lives miles away and cannot come at a moment's notice. Fourth, if infection breaks out the nurse is not available, that medical men fear the introduction of women doctors, but they are wrong; the women doctors would prove valuable aids. I use the word "doctor" instead of nurse because the training is different and the knowledge wider. The woman doctor would call in the man doctor in serious cases. She could work under him and owe her appointment to him if it was ordered that the medical man of a district might grant her a working certificate. The woman doctor or doctoress might also earn a small fee as medical inspector of village schools.

As to the question of chemists being consulted instead of medical men, it is widely done. I mentioned the fact purposely. There are many trifling ailments for which it is unnecessary to send for a medical practitioner. The nursing of the middle-class and poor can only be systematically worked from a centre. The technical education funds now given to agricultural, horticultural, and other scholarships, or spent in superfluous education in minor sciences, might more worthily be applied to establishing a county nursing home worked on sound business-like principles so as to be self-supporting. Our poor do not want pauperising. They are willing to pay, but no hospital nurse is fitted for village work.

I hope you will find space for this letter as in the article referred to you only quoted a few sentences.

I am, Sirs, yours truly,

Suthamstead-park, Nov. 22nd, 1897. E. R. THOYTS.

*** Miss Thoyts has not comprehended our remarks. An inferior order of general practitioners is not required.—ED. L.

Professional Etiquette.—The case submitted to us forms one more example of the ills that arise from medical men entering into bonds with lay employers. C's agreement being a more advantageous one to the society than B's the society naturally favoured C at the expense of B. We do not see why C should not obtain the material advantage of a house as he is under the material disadvantage of a strict contract.

THE PROTECTION OF BIRDS.

THE International Congress on the Protection of Birds, inaugurated at Aix-en-Provence on Nov. 9th under the auspices of the Ligue Ornithophile Française, of which M. Louis-Adrien Lerat is the president, was concluded on Nov. 13th. The protection of insectivorous birds useful to agriculture was the chief subject of discussion and it was decided that the resolutions adopted should be forwarded to the Governments of Europe through the French Minister for Foreign Affairs. Numerous French and Italian agricultural, horticultural, and sporting societies sent delegates to the Congress. Mr. and Mrs. Lemon, of Hillcrest, Redhill, Surrey, represented the Selborne Society and the Society for the Protection of Birds.

THROWING STONES AT A TRAIN.

APROPOS of this subject, upon which we commented strongly in our issue of Oct. 23rd, we are glad to see that a boy, aged fourteen years, was, at Brentford police-court upon Nov. 12th, sentenced to hard labour for one month for throwing a stone at a train on the London and South-Western Railway. This is good as far as it goes, but a sound birching would have been better still.

F.R.C.P. Edin., &c.—The district council are bound by law to pay for certificates of notification sent to them by any medical practitioner, without any limitation as to the practitioner in question being an assistant to another one or not. As regards medical officers of health we have quoted in our reprint of articles on "Difficulties under the Infectious Disease (Notification) Act" the decision of the Local Government Board to the effect that where a medical officer of health is "attending on or called in to visit the patient," he is entitled to his fee for notification "just as if he were an ordinary medical practitioner." Provided the visit in question is definitely one of attendance on the patient and not one of inspection as health officer the fee should, in our opinion, be always claimed. Failure to demand a fee legally due under the circumstances named can only be regretted on the ground that it is liable to lead to difficulties such as those which in this case affect not the health officer but another medical practitioner.

A BOOK ON STAMMERING.

To the Editors of THE LANCET.

SIRS,—Could you or any of your readers tell me of a small but reliable book on Stammering suitable for a schoolmaster to read who seeks to benefit a pupil? I am, Sirs, yours faithfully,

Nov. 22nd, 1897. W. R. K.

AN EXPLANATION.

THE Secretary, Bournemouth Hydro Establishment, recently forwarded to some members of the medical profession in London a magazine containing a sketch relating to the institution. She omitted to place sufficient stamps on the wrappers. We are asked to state that she is anxious to hear from any recipient who may have had to pay additional postage as she will at once forward four penny stamps.

MALIGNANT SCARLET FEVER.

To the Editors of THE LANCET.

SIRS,—I think the following sad case may be interesting to your readers. I attended two cases of scarlet fever in a house in this city. After these were convalescent the authorities stoved the house—it was supposed most efficiently. About a month after this a message was brought to my house—not one of urgency, but merely "would I call on my round." On reaching the house the mother told me that the patient, a girl, was unconscious. I at once went up to see the patient. On feeling her skin I was astounded. It felt like putting one's hand on a red hot coal, and on taking her temperature my thermometer registered 110½°F. The whole of the body was covered by an ecchymosed rash and the patient was quite unconscious and collapsed.

It is the first case of malignant scarlet fever I have seen and I hope it will be the last. The girl seemed to have no earthly chance, the whole disease only lasting twenty-four hours.

I am, Sirs, yours faithfully,

THOS. J. WALKER, L.R.C.P. & S. Edin., &c.

Burley Mount, Leeds, Nov. 21st, 1897.

FAT IN HEALTH AND DISEASE.

THE ONLY FAT FOOD
IS
SAVORY & MOORE'S
PANCREATIC EMULSION.

FAT forms about 18 per cent. of the adult human body. It is stored up as a reserve in adipose tissue, and the loss falls chiefly upon this in starvation or in the wasting of disease, so that nearly the whole of the fat may disappear. Adipose tissue is very fluctuating in quantity. A large amount may disappear in a very short space of time, and within an almost equally short period the quantity present in a body may be several times multiplied. Stored-up fat comes from the fat of food, which in an ordinary diet varies from one to two and a half ounces. It is also formed from carbo-hydrates, such as starch and sugar, but both these substances, especially sugar, are frequently clinically counter-indicated. Fat is naturally indicated in all cases of wasting and loss of weight, and, conversely, a tendency to corpulency may be counteracted by restricting the fats and carbo-hydrates and increasing the proportion of proteid which augments the general metabolism of the body.

Digestion consists in the conversion of non-diffusible proteids and starch into more diffusible peptone and sugar, and in the emulsifying of fat by its division into minute particles. In certain diseases the action of the pancreas on fat is weakened, if not entirely suspended, with the result that much of the fatty part of the food passes through the intestine undigested.

The action of the healthy pancreas on fat is chiefly an emulsifying one, though under some conditions there is also an appreciable splitting up of the fat into its component fatty acids and glycerine. The fluid containing the elaborated product of digestion in its final stages—viz., chyle—owes its whiteness and opacity to fat, of which it often contains, after a meal, as much as 5 per cent., the fat existing in the form of exceedingly minute spherules or granules, far smaller than any globules to be seen in milk. It is the most perfect emulsion known, and is the only one that is not broken up by the action of ether.

The immense importance of maintaining the proper proportion of fat in chyle will be realised when we consider that an amount of chyle equal to half the whole blood of the body may pass through the lacteals from the alimentary canal in the twenty-four hours. The formation of an Emulsion of Fat, *identical with the emulsion as it exists in chyle passing through the lacteals*, has now been arrived at, outside the body, by the action of the pancreas. This Emulsion is known as *Pancreatic Emulsion*, and by its means we can present the fat of food in the condition necessary for immediate assimilation where the natural power of emulsifying fat is lost or impaired.

In disease arising from defective nutrition, and in phthisis and all scrofulous conditions, fat is often found of the greatest benefit. It is also invaluable in the convalescence of acute disease, and as a tonic to the nervous system in neuralgia and nervous debility. It is obviously an advantage in a dietary to give solid animal fat, which, like human fat, contains a considerable proportion of stearin and palmitin, as well as olein, in preference to a fat like cod-liver oil, which consists almost entirely of olein. "PANCREATIC EMULSION" provides the natural fat of food, emulsified so that it can be assimilated and absorbed with the greatest ease. Experience shows that it is free from the drawbacks so often attending the administration of cod-liver oil, and that it can be continued for any necessary length of time without disagreeing or causing nausea or diarrhœa, and that a rapid increase of weight and immediate improvement in health result from its use.

The Emulsion is a perfectly neutral one, formed solely by the action of the pancreas, is absolutely unobjectionable in taste, easily miscible with fluids, and of the consistence of Devonshire cream. It keeps sweet and good for years in any climate and may be obtained of all the principal Chemists throughout the world.

In bottles 2/6, 4/6, and 8/-, with special terms to Hospitals and Infirmaries.

"APENTA"

THE BEST NATURAL APERIENT WATER.

Bottled at the Springs, Buda Pest, Hungary, under Eminent Scientific Supervision.

CONCLUSIONS from Clinical Observations on the action and value of APENTA WATER in Obstinate Constipation by Professor W. S. BOGOSLOWSKY, Director of the Pharmacological Institute of the Moscow University, &c., &c :—

"Systematic treatment with APENTA Water is especially indicated for Constipation produced by Atony of the Bowels, and Apenta possesses without doubt this advantage over other aperients, that its use does not give rise to subsequent constipation.

"By suitable doses of this water the bowels act freely and considerable quantities of bile are evacuated. The action of APENTA Water is more gentle than that of the bitter waters most known with us because it contains less calcium sulphate and no magnesium chloride. It is probably due to this circumstance that the crampy pains generally observed when aperients are employed are entirely absent in the case of APENTA.

"The efficiency of APENTA as a remedy for the systematic treatment of Obesity in general is clinically established."

A Translation of the Report of Professor W. S Bogoslowsky, read at the Meeting of the Society for the Preservation of Public Health, Moscow, will be forwarded on application to

An Inaugural Address

ON THE

PROBLEM OF THE CONSUMPTIVE POOR.

Delivered at the Opening of the Session of the Ulster Medical Society in the Museum, Belfast, on Nov. 4th, 1897,

BY JAMES ALEXANDER LINDSAY, M.A., M.D. R.U.I., M.R.C.P. LOND,

PRESIDENT OF THE SOCIETY; PHYSICIAN TO THE BELFAST ROYAL HOSPITAL; CONSULTING PHYSICIAN TO THE ULSTER HOSPITAL, BELFAST; FORMERLY ATTENDING PHYSICIAN TO THE CONSUMPTIVE DEPARTMENT, THRONE HOSPITAL, BELFAST.

GENTLEMEN,—Michelet, the great French historian, once expressed the belief that the civilised races of mankind would eventually die out as the result of the ravages of phthisis and I have little doubt that if the rapid growth of population and the increasing tendency for men to mass themselves together in large urban centres had not been accompanied by a corresponding development of sanitary science, a wider recognition of the principles of hygiene, and a higher standard of comfort the prediction of Michelet would have been before now in a fair way of fulfilment.

Let us endeavour to form some rough estimate of the probable amount of phthisis in existence. No precise data can be obtained for a calculation of this kind, but the number of deaths from this cause are available and a comparison of these with the probable duration of the disease will afford the basis for a conclusion sufficiently probable for the purpose which I have in view. In the year 1890 Dr. Arthur Ransome estimated the deaths in the British Islands from tubercle in its various forms at 70,000. He also stated that "in the form of phthisis at ages between fifteen and forty-five—the most useful stages of human existance—it kills more than a third of the people who die and nearly half between fifteen and thirty-five." Dr. Chas. Denison, of Denver, computes that 40 per cent. of the deaths in New York between the ages of twenty years and forty years are due to phthisis. The returns of the various insurance companies show that between the ages of twenty years and fifty years phthisis is responsible for a fourth, and in some companies a third, of the deaths—a sufficiently striking fact when we recollect that these are picked lives. I find by the Registrar-Generals' Reports for 1895 that the deaths from phthisis in that year in England numbered 42,490, in Scotland 7688, and in Ireland 9768, making a total for the kingdom of 59,946. These figures are considerably under the average for the last fifty years, but let us assume that the annual deaths from phthisis in the British Islands are about 60,000. Can we from these figures form any sort of estimate of the probable number of cases of the disease existing at the same date in the same area? In order to do so we should require to determine the following points: (1) the average duration of fatal cases; (2) the number of cases which recover; and (3) the number of phthisical patients who die from causes other than their pulmonary malady—e.g., accident or intercurrent disease.

It is only as regards the first of these points that any definite information is procurable. Laennec and Louis estimated the average duration of the disease at two years, a calculation which still exerts some influence upon medical opinion although it has been long ago shown to be erroneous. Pollock found that at the end of two and a half years the majority of his hospital patients had still a fair expectation of life. C. J. B. Williams and Theodore Williams found that amongst 1000 cases occurring in the upper classes the average duration of 198 cases terminating fatally was seven years and eight months, and of the remaining 802 who were still living the average duration was eight years and two months. Against the rapid cases we must set the very chronic cases which are not rare. Wilson Fox mentions cases recorded by Laennec, Andral, Portal, Bayle, Flint, Walshe, and Williams where the disease lasted twenty, thirty, and even forty years. I had recently under my care a gentleman with well-marked affection of both apices in whom the disease set in with violent hæmorrhages just twenty years ago, in the autumn of 1877. He is still in fair health. I believe such cases, although exceptional, are not of excessive rarity and a due consideration of them must lead us to expand considerably our ideas regarding the average duration of the disease. Putting all the facts together I am inclined to think that the average duration of phthisis among all classes may be put safely at from three to four years. Sir Richard Douglas-Powell, to whom I referred this point and whose authority will be universally recognised, writes me that he thinks this calculation "quite within the average mark." As regards the proportion of cases which recover they probably constitute a by no means negligable quantity. To this subject I shall hereafter return. The number of phthisical patients who die from intercurrent maladies or from accident and violence must be considerable, but no statistics on the subject are available. Allowing due weight to all these considerations and admitting that the conclusion reached is somewhat speculative we may fairly estimate the number of persons suffering from phthisis in the British Islands at *not less than a quarter of a million*. That this calculation is probably under rather than over the mark will become evident if we consider the most authoritative figures available regarding other countries. Professor Leyden in an address delivered at the Congress of Budapest on Sept. 7th, 1894, calculated the deaths from phthisis in the German Empire at 170,000 per annum, the deaths in Berlin being 4590. From these facts he concludes that the number of phthisical patients alive in Germany exceeds a million. A recent German Commission estimated the sufferers from tuberculous disease at 1 in 50 of the population. I have no means of forming a correct judgment as to the accuracy of these calculations and it would be presumptuous in me to criticise the views of so distinguished an authority as Professor Leyden. I merely wish to point out that my own estimate as regards this country probably errs on the side of caution.

It is important with a view to our present purpose to form some rough estimate as regards what proportion of this quarter of a million of phthisical patients occur among the upper and well-to-do classes, and what proportion among the classes which usually seek hospital relief. No materials exist for a satisfactory calculation of this kind, but as some concrete figure is necessary, not so much for the purpose of reinforcing an argument as to give some degree of definiteness to our ideas, let us calculate the former proportion at one-fifth and the latter at four-fifths. If these calculations are well-founded—and they are put forward with unfeigned diffidence—we reach this conclusion—that there are in these islands at the present time about 200,000 persons suffering from phthisis who might be expected to seek hospital relief. What provision is made for dealing with this vast mass of misery and suffering? London has four chest hospitals with accommodation, as Dr. Theodore Williams informs me, for about 640 patients. There are chest hospitals, consumption hospitals, or sanatoria at Bournemouth, Ventnor, St. Leonards, Torquay, Liverpool, Manchester, Newcastle-upon-Tyne, Bridge of Weir (Renfrewshire), Edinburgh, Newcastle (Co. Wicklow), and Belfast. The total accommodation in these institutions would appear to be about 1160 beds. So that, allowing for the fact that many of these beds are frequently occupied by cases of heart disease, bronchitis, &c., we reach the startling conclusion that the nation provides about one bed for every 200 phthisical patients who might be expected to demand and require hospital relief. I do not overlook the obvious fact that many of these phthisical cases enjoy a certain fair amount of general health and that a considerable number of them are earning their living, but it will be admitted that there are very few phthisical patients among the lower classes who either do not from time to time require hospital treatment for one of the many complications of their malady or who would not benefit by a temporary sojourn in a well-organised sanatorium. To fortify my position and protect myself against the suspicion of exaggeration permit me to quote the statement of Dr. Hermann Weber that "well-arranged special hospitals for the treatment of consumption have accommodation only for one sufferer in a thousand." My calculation is rather less appalling, but it shows a condition of things which will be admitted to constitute a dark blot on our boasted civilisation.

To what causes are we to attribute this patent gap in the network of charity which, happily, in this country covers the greater part of the field of suffering? First may probably be placed the general feeling of hopelessness in face of a problem which seems to present insuperable difficulties. A further and not less important reason for the

Digitized by Google

general apathy regarding the pitiable condition of the phthisical poor is, as I fear we must all admit, the divided counsels and doubtful voice of the medical profession on this subject. The public naturally look to us for guidance in a matter of this kind and that guidance has not been given—at all events with sufficient emphasis and unanimity to make it effective. It would, however, be most untrue and unjust to assert that the medical profession has been entirely silent on the subject. Most of the special workers in this field of practice have from time to time raised a warning voice and endeavoured to point out a better way; but the general mass of the profession has not made its influence felt. What we need is a consensus of medical opinion comparable to that which now upholds the principle of compulsory vaccination and insists upon the erection of special hospitals for fever. Is it too much to hope that such a consensus of opinion may be attained amongst us as to the best solution of the problem of the phthisical poor remembering what Alfred de Musset once said: "To formulate general ideas is to change saltpetre into powder"?

Let us first of all inquire what is being done elsewhere with regard to this question, to which end I will endeavour to give a brief sketch of the present state of accommodation for phthisis in different parts of the world, distinguishing between those institutions where the patient has to pay for the cost of his maintenance and those designed especially for the poor.

Germany.—Of sanatoria for paying patients we may enumerate the following:—1. The Brehmer Sanatorium at Görbersdorf in Southern Silesia. This institution is situated on the Riesengebirge at an elevation of 561 metres above sea-level. Its erection was begun in 1859 and the principles and methods therein developed so successfully by Dr. Brehmer have been the seed from which all the modern developments in the treatment of phthisis in Germany have sprung. In the near vicinity of Görbersdorf there are several subordinate sanatoria—viz, the Sanatorium Roupler and the Sanatorium de la Comtesse Puckler. 2. The Falkenstein Sanatorium near Cronberg on the Taunus Mountains, twenty-five kilometres from Frankfort-on-the-Main. This institution was founded in 1874, and under the able direction of Dr. Dettweiler it has achieved great success and well-deserved repute. I had an opportunity of visiting Falkenstein a few years ago and I have recently been in communication with Dr. Dettweiler, to whom I am indebted for much valuable information. The sanatorium is situated at an elevation of 420 metres above sea-level and is surrounded by pine forests. The situation is open and airy, commanding a fine prospect of the valley of the Main, and there is a fair amount of shelter. 3. Hohenhonnef on the right bank of the Rhine between Linz and Bonn. This sanatorium was inaugurated in 1892 and is one of the finest and most complete in Germany. 4. Reiboldsgrun in the Erzgebirge Mountains of Saxony was founded in 1873. This sanatorium is surrounded by pine forest and the soil is volcanic. The elevation is 690 metres. 5. St. Blasien (elevation 772 metres), Badenweiler (elevation 420 metres), Nordrach and Schömberg (elevation 650 metres) are all in the Black Forest. 6. The Harz Mountain Sanatoria—viz., Saint-Andreasberg (elevation 600 metres), Rehberg (elevation 150 metres), and Altenbrack.

Other institutions more or less devoted to the treatment of phthisis exist at Kissingen, Aussee, Baden-Baden, Blankenstein, Berkd, Dillenburg, Meran, Ems, Brückenau, Sophienbad, Schönberg, &c. Of hospitals for the phthisical poor Germany reckons the following: 1. Falkenstein. This is a small institution close by the Dettweiler Sanatorium, already described, which is for pay-patients. 2. Ruppertshain, near Königstein, about an hour's drive from Falkenstein. 3. The Malchow Hospital, in the neighbourhood of Berlin. 4. At Saint-Andreasberg, in the Harz Mountains, where (as already mentioned) there is a sanatorium for pay-patients. A small hospice also exists for the poor.

Several of the German towns—e.g., Bremen, Stettin, Dresden, Hanover, and Worms—either possess or have in contemplation hospitals or sanatoria for poor phthisical patients.

Switzerland.—1. Davos, elevation 1560 metres, so well known for the successful treatment of phthisis, possesses several sanatoria. The chief one is that under the direction of Dr. Turban. There are also the Maison des Diaconnesses and the Villa Pravignan. 2. Aroza, not far from Coire, at an elevation of 1856 metres, possesses a sanatorium where the same methods of treatment are pursued as those found efficacious at Davos. 3. Leysin, elevation 1450 metres, above Aigle in the Rhone Valley. 4. Wiessenbourg, in the Valley of Timmen, to the west of the Bernese Alps. The elevation is 890 metres.

The above are for pay-patients. Of sanatoria for the phthisical poor Switzerland reckons the following: 1. The sanatorium at Schwendi overlooking Lake Thun. This was erected by the town of Berne in commemoration of the sixth jubilee of the Swiss Confederation. 2. The sanatorium at Bâle. This town also possesses a sanatorium at Davos-Dörfli recently erected at a cost of £20,000. Other towns and cantons of Switzerland have followed or are about to follow the excellent example of Berne and Bâle—e.g., Glarus, Zurich, Geneva, Vaud, Neufchatel, Saint-Gall, the Grisons, and Zofingen. There is good reason to hope that in a short time Switzerland will possess a complete chain of hospitals for the phthisical poor, thus affording a proof of what even a very poor country can effect in the cause of charity.

Austria-Hungary.—The only Austrian sanatorium of which I can obtain any information is that of Neu-Schmecks in the Carpathian Mountains at an elevation of 1004 metres. A hospital for poor phthisical patients is projected at Alland, near Vienna.

Norway.—The sanatorium Tousaasen is situated between Bergen and Christiania at an elevation of 600 metres. The Norwegian Parliament has recently decided to devote two disused leper hospitals to the treatment of poor phthisical patients.

Russia.—There are the following sanatoria: (1) Oranienbaum, near Peterhof; (2) Slawata in Volhynia; (3) Halila in Finland; and (4) Yalta in the Crimea.

Italy.—Professor Tommasi Crudeli, of Rome, writes to me: "No special hospital for consumptive patients has till now been founded in Italy. They have only some special and isolated sections in many of the general hospitals. There is some talk now of building some sanatoria in the Alps, but till now it is only a remote hope and no sanatorium of the kind exists in Italy." It should be remembered, however, that Italy possesses quite a number of hospitals scattered along the Adriatic and Mediterranean coasts for the treatment of tubercular disease of bones and joints.

France.—The following sanatoria exist: 1. Angicourt, in the department of the Oise. 2. Canigou, in the Pyrénées Orientales. 3 The Sanatorium Touraine, in the environs of Tours. 4. The Ormesson Hospital, on a plateau above the valley of the Marne. 5. The Hospital of Villiers-sur-Marne. 6. The sanatorium at Saint-Martin-Lantosque, near Nice, at an elevation of 1000 metres.

America.—The following sanatoria exist: 1. Saranac Lake Sanatorium, in the Adirondack Mountains (elevation 1600 ft.), under the direction of Dr. Trudeau, founded 1884. This is the best-known sanatorium in America and has been very successful. 2. The Sharon Sanatorium (elevation 300 ft.), near Boston. 3. The Ashville Sanatorium, in North Carolina (elevation 2250 ft.). 4. The Chestnut Hill Consumption Hospital, Philadelphia. 5. The Bellevue and the Gleckner Sanatoria, in Colorado. As regards the provision for poor patients Dr. Osler writes me from Baltimore: "No attempt has been made to provide proper hospitals for consumptive poor in America."

For many of the above facts relating to foreign sanatoria I am indebted to the works of Knopf and Léon Petit and to Dr. R W. Philip of Edinburgh. The above enumeration makes no pretence to completeness as new institutions are constantly springing up. As regards our colonies a movement is at present on foot in Sydney, New South Wales, to provide proper hospital accommodation for phthisis, but the matter is still only in the tentative stage and some difference of opinion appears to exist as to the best method of procedure. One party advocates the foundation of a central institution in the city with branches in the country while the other would rely solely upon small cottage hospitals.

Let us return to the case of Germany and Switzerland, where the most substantial progress has been made. Dr. Brehmer, of Görbersdorf, and Dr. Dettweiler, of Falkenstein, have been the great pioneers of the modern movement and to their teaching and example we owe a large debt. The broad principles which underlie their methods are identical and may be summarised as follows: That phthisical patients should be treated in special institutions erected for the purpose on a healthy, airy, fairly sheltered, and if possible elevated situation; that the treatment should be essentially hygienic and dietetic, medicinal treatment and

Digitized by Google

specific remedies being assigned a very subordinate place; that only early cases, or those offering a fair hope of cure, permanent arrest, or at least substantial benefit, should be eligible for admission; that strict medical control and the most vigilant supervision of the patients' habits, occupations, and amusements should be enforced, and that every precaution should be taken to destroy the virus and limit the dissemination of the disease. It is to be observed that the sanatoria in which these principles have been successfully carried out present many variations as regards situation and climate. Görbersdorf, the parent institution of the kind, is at an elevation of 1700 ft.; Falkenstein, 1300 ft.; Hohenhonnef, 770 ft.; Rehberg, in the Harz Mountains, 480 ft.; and others at still lower levels. The climate of the Silesian Mountains, or of the Taunus range, or of the Harz Mountains, or of the Rhine valley cannot be considered as especially favourable for phthisical patients, yet, as we shall see, the results of treatment obtained in these localities are on the whole encouraging and show that in a certain considerable proportion of cases the disease can be successfully combated without removal to the Alps, Egypt, South Africa, Colorado, Australia, or any of the other localities which have obtained a special repute in the treatment of phthisis. There is the more need to emphasise this point as our efforts to provide ampler accommodation for phthisis in this country are sure to be met with the objection that the climate is unfavourable and that therefore nothing can be done. This is one of those half truths which are often so much more dangerous than actual falsities. The best answer to this objection is to be found in the example of Germany. Without denying or minimising the considerable influence which climate exercises upon phthisis it is important to recognise that good results may be obtained even where the climatic conditions are only moderately favourable. It is obvious that for the great mass of phthisical patients a distant and expensive journey and a residence in a foreign country are quite impracticable.

These methods of treatment have now been in vogue in Germany for more than a quarter of a century and the number of cases thus treated has been very large. There should be no difficulty in forming a correct estimate of the value of these methods and whether they are suitable for imitation. The authority and reputation of Dr. Brehmer and Dr. Dettweiler stand so high that their reports may be regarded as conclusive, but it is only fair to add that these institutions have been repeatedly visited by British physicians who have fully corroborated the favourable reports of these gentlemen. Dr. Hermann Weber has given testimony in this sense. Dr. Dettweiler writes to me (Falkenstein, Oct. 16th, 1897) as follows: "At the Falkenstein Sanatorium we reckon about 30 per cent. of absolute or relative cures. In the latter class are comprehended those cases which, although restored to good general health and capability for work, still show some slight signs of remaining disease. The proportion of patients who derive signal benefit from the treatment and who are able to return for a longer or shorter time to their labours in the world is fully 45 to 50 per cent. Even severe cases often obtain surprising benefit, but it is not desirable to send cases characterised by hectic fever, much diarrhœa, amyloid degeneration and great loss of flesh." These statements touch the very kernel of the subject of any national provision of hospitals or sanatoria for phthisical patients. Is it true that a certain material proportion of cases can be cured and that a much larger proportion can be restored to years of useful and fairly comfortable life? The whole case stands or falls with these propositions and therefore I shall ask you to consider with me for a little the evidence which is available regarding the curability of phthisis.

Gentlemen, I think the time has come when we should cease to speak of the cure of phthisis with bated breath as if it were a vain pretence or a mere hallucination. Evidence is accumulating both on the clinical and on the pathological side to prove that a considerable number of persons pass through an attack of pulmonary tuberculosis, recover their health and live to the average period, ultimately dying from some other malady. I take the following statistics from Wilson Fox. In the first report of the Brompton Hospital, which included 535 cases, cure or complete arrest was recorded in 5·6 per cent. In the second Brompton report, which included 6001 cases, cure or complete arrest was recorded in 4·1 per cent. Williams records cure in the case of 3·1 per cent. of 700 patients who remained in England. Flint records cure in 12·1 per cent. of 74 patients who tried various climates, especially the sea-voyage. Hermann Weber records cure in 24·5 per cent. of 75 patients who tried the high altitudes. Clifford Allbutt's proportion of cures among patients resorting to the high altitudes was 22·5. Spengler, of Davos, had 21·3 per cent. of cures in 342 cases. These figures cannot be dismissed with a smile of incredulity. The writers in question are among the highest authorities upon pulmonary disease and if we cannot accept their figures there is an end to all statistical evidence in medicine. I should like especially to emphasise the fact that 4 or 5 per cent. of cures were obtained among patients who had no change of climate. Again, it has been found that a large proportion of persons dying from accident or old age bear traces in their lungs of having passed successfully through an attack of pulmonary tubercle. How often, also, do we meet in practice with elderly patients suffering from various maladies who tell the story of repeated pulmonary hæmorrhages in youth or of having been supposed to be "far gone in consumption" and yet recovered. It has been too much the habit to put these cases down to errors in observation and mistakes in diagnosis. The newer light which we have obtained upon the subject justifies the belief that no inconsiderable proportion of these cases are instances of arrest of the disease owing to tubercle becoming obsolescent.

The utility of special institutions for the treatment of phthisis does not depend solely upon the consideration that a certain number of cures are effected in them. We must remember the large proportion of patients who cannot, unhappily, be cured, but who can be restored to comparative health and well-being and enabled to resume for a longer or a shorter period their place in the world. No one who has studied the subject will deny that this class is a considerable one. To prolong life when it is doomed to suffering and uselessness may well seem a doubtful benefit, but the patients who rally from an attack of phthisis are not always, perhaps not usually, in this sad plight. Often they regain a very considerable enjoyment of life and the difficulty is to persuade them that their condition is precarious and that a relapse is probable. Not infrequently if they can be induced to select healthy occupations a considerable period of useful existence is before them. The very important subject of how far these special institutions may be made available for preventing the dissemination of the infective material of the disease and so limiting its propagation must be considered in a little detail. Many have been the fluctuations of popular and professional opinion upon this important subject and although we are probably nearer unanimity at present than we have ever been before we are still far from having attained to it. A belief in the contagiousness of phthisis has long prevailed in Italy and Spain more perhaps as a popular opinion than as a scientific doctrine. The contagionist view which received a great accession of strength from Koch's discovery is now widely prevalent upon the continent, especially in Germany, but never seems to have taken deep root in this country. The results of the inquiry instituted by the Collective Investigation Committee of the British Medical Association were equivocal. A large majority of the medical men how responded had seen nothing to warrant a belief in the contagiousness of the disease, but a respectable minority took the opposite view. The cases which were chiefly relied on in support of the contagionist view were those in which the disease appeared to have been transmitted from husband to wife or from wife to husband. There were 188 such cases reported and it is notable that of these 119 were cases of supposed transmission from husband to wife and only 69 from wife to husband. Dr. Longstaff in his work "Studies in Statistics" has, however, shown that these cases of phthisis in husband or wife when the other partner had been previously affected are not more numerous than would arise on the general principle of averages without postulating any theory of contagion. I content myself with giving my opinion that the direct transmission of phthisis from one individual to another is a rare event. Not the less, however, is the disease in all probability infective. All the facts of the case seem most easily explicable on the theory of Koch and Cornet that phthisis is chiefly disseminated by means of dust rendered infective by the drying and pulverisation of sputum from phthisical cases. According to this view the infectiveness resides rather in the rooms occupied by patients than in the patients themselves and the disposal of sputum becomes a question of the first

Digitized by Google

importance. That the inhalation of infected dust is the usual method by which phthisis is contracted is at least a highly probable theory, but the report of the recent Royal Commission on Tuberculosis gives ground for believing that the use of tuberculous meat and of milk derived from cows with tubercle of the udder is at least a possible mode of origin of the disease. If we adopt the views of Koch and Cornet the argument in favour of special institutions for phthisical patients is much strengthened. The best prospect of arresting this scourge of humanity lies in preventive measures and no preventive measure is so hopeful as one which would tend to enable us to limit the *materies morbi* to institutions where it could easily be deprived of all infective properties.

The amount of accommodation which would be required to grapple with the huge mass of phthisis existing amongst us would no doubt be enormous, but in that halcyon future—

> "When wealth no more shall rest in mounded heaps,
> But smit with freer light shall slowly melt
> In many streams to fatten lower lands"—

some such scheme as the following will probably be adopted. Every city, town, and commune above a certain rate of population, will have a central hospital for phthisis with smaller branches in the most suitable adjacent locality either in the hills or at the seaside. The function of the central institution will be to receive cases in the first instance, to treat urgent symptoms, such as hæmorrhage, to select the cases suitable for transference to the various coördinated sanatoria, to promote research, and to educate the community in preventive measures. No cases will be received except such as hold out some prospect of decided improvement, advanced and hopeless cases being relegated to homes for incurables. The actual treatment of cases will be undertaken chiefly in the various sanatoria and will probably follow the lines adopted at Görbersdorf and Falkenstein. The following results may fairly be expected: 1. Cure or complete arrest in a certain proportion of cases which will probably be somewhere between the 4 or 5 per cent. hitherto obtained in this country and the 30 per cent. claimed by Dr. Dettweiler at Falkenstein. 2. Material improvement, permitting the patient to resume his work in the world and restoring him to fairly good health for a longer or shorter period. This proportion will probably be a considerable one. 3. The relief of suffering in cases which fail to respond to treatment or make any definite rally. 4. The education of patients in hygienic and dietetic principles and in preventive measures, especially the disposal of sputum. 5. The prevention of infection.

We may derive much encouragement in the fight against phthisis not only from the fact that the efforts made to stamp out the kindred disease of leprosy have been crowned with success but also from the fact that the disease is already steadily on the decline. In the quinquennium 1855–59 there died from phthisis in England and Wales 2648 persons per million living. Twenty years later, in the quinquennium 1875–79, the number of deaths per million living had fallen to 2117, a decrease of no less than 20 per cent. in twenty years. The latest available figures show that this decrease is still happily going on. As during the same period there has been an increased mortality from respiratory diseases other than phthisis it might at first sight appear that the apparent decline in mortality from phthisis was really due to greater precision in diagnosis and the transfer of cases from one column to the other. Dr. Longstaff and Dr. Newsholme have shown conclusively that this explanation will not harmonise with the facts. The mortality from phthisis has decreased at all ages, while the mortality from respiratory diseases has only increased under five and over thirty-five years of age. We may take it as certain that phthisis is sensibly on the decline in the British Islands, and there is the more encouragement to perfect our weapons and urge a more active warfare against it. Other measures in addition to those advocated in this address will be required, such as improvements in the dwellings of the poor, the regulation of unhealthy occupations, the dissemination among all classes of sound views on hygiene, and the means necessary for the prevention of infection, the inspection and control of our meat and milk-supply, the special nurture of children of tuberculous ancestry and the like. But I regard the adequate provision of special institutions for the treatment of the disease as an indispensable item in the programme of preventive measures. The present system of treating phthisis in general hospitals is on many grounds to be condemned. It is certainly bad for the phthisical patients, probably bad for the other patients. It was strongly condemned by the International Congress on Tuberculosis a few years ago and it is quite time for all hospital physicians and those interested in hospital administration to make a resolute stand against it. No phthisical patient ever recovers in a general hospital and his treatment there—with the exception of the relief of urgent symptoms—is little better than a farce.

Medical science and advancing civilisation have practically stamped out the plague, kept cholera successfully at bay, and robbed leprosy, small-pox, and typhus fever of most of their terrors. They are slowly beginning to make headway against a greater foe than all—tuberculosis. That its gradual arrest and final extinction are not only happy possibilities but practical certainties I for one firmly believe. I believe further that the means for attaining this end are already known and that we see the road which must be followed in order to reach the desired goal. That road is long and toilsome—worse still, it is extremely expensive—but the call to follow it is imperative and will some day become irresistible. The duty laid upon the medical profession is to point the line of advance and to lead the van. The results may not fully appear in our day, but "*arborem serit diligens agricola quarum aspiciet baccam ipse nunquam.*" If we are told that these proposals are vain and chimerical, that their realisation would put an intolerable load on the back of already overburdened humanity, let us reply in the glorious paradox of the great prophet-critic of this age: "You tell me what we ask is impossible. That may be so. I can only answer that it is indispensable."

A Lecture
ON
THE PULSE.

Delivered at St. Bartholomew's Hospital on Nov. 11th, 1897, preliminary to the Course of Lectures on Medicine,

BY NORMAN MOORE, M.D. CANTAB., F.R.C.P. LOND.,

LECTURER ON THE PRINCIPLES AND PRACTICE OF MEDICINE; ASSISTANT PHYSICIAN TO THE HOSPITAL.

GENTLEMEN,—The object of these lectures on the Principles and Practice of Medicine is to teach you how to recognise disease, how to forecast its course, and how to treat it. The patient or his friends offer you these complicated questions for solution in a particular case. You have to make a diagnosis and a prognosis and to carry out a method of treatment. You cannot take too much trouble to find out what is the matter. When you come to have many patients and to think over the cases in which your diagnosis was wrong you will find that in most of them the solution of the question was within reach had you but noticed and duly considered everything that was before you.

The first duty when you come to the bedside of a patient is to enter into such friendly relations with him as his condition allows. "A good bedside manner" is sometimes mentioned with scorn as an unworthy aid to the practice of medicine. I advise you to think it of importance. It is not an artifice—it consists in feeling and showing kindness to the patient. If he sees at once that you care to relieve him, are intent upon finding out what is the matter with him, and are willing to take any trouble to do so, he will in most cases at once give you his confidence and thus help you to an accurate diagnosis. No other art is needed than that you should do for him all that you would wish done for yourself were his illness your own. English literature contains one perfect description of the way to approach a patient. It is in Sterne's story of Le Fevre, a poor lieutenant who had been taken ill at a village inn and whose illness had been made known to Captain Toby Shandy, a retired officer of Marlborough's, living near the village, by the captain's devoted servant, Corporal Trim, who had seen the patient's son in the kitchen of the inn the night before. "The sun looked bright the morning after to every eye in the village but Le Fevre's and his

Digitized by Google

afflicted son's; the hand of Death pressed heavy upon his eyelids—and hardly could the wheel at the cistern turn round its circle,—when my uncle Toby, who had rose up an hour before his wonted time, entered the lieutenant's room, and without preface or apology sat himself down upon the chair by the bedside, and independently of all modes and customs opened the curtain in the manner an old friend and brother officer would have done it and asked him how he did, how he had rested in the night, what was his complaint, where was his pain, and what he could do to help him." When in the way most suitable to the particular case and most natural to you you have entered into relations with the patient your first observation will probably be to feel his pulse. So long has this been associated with clinical investigations that a hand feeling the pulse is one of the bearings in the coat-of-arms of our London College of Physicians. In the quaint terms of the Elizabethan heralds, "The chefe an arm charnois out of a clowde argent and azure with the rase of the son golde with a cuffe ermin the hande felenge the powlse of an arme in fesse charnois as more plainely appeareth depicted in the margent."[1] Hippocrates, to whose writings we look for the first beginnings of so many parts of clinical medicine, was clearly accustomed to feel it, though there are not many passages in his books where it is mentioned. He speaks of a slow pulse in lethargy, notices that the pulse has a relation to age and that it is quick in fever. He is said first to have applied the word σφύγμος to the beating of an artery as distinct from any general pulsation, or throbbing as we should say. Herophilus of Alexandria, with whose torcular or wine-press we all became acquainted so early in our studies, wrote on the pulse,[2] and so did many other authors of whom we know little but in quotations. The first physician whose complete writings we possess on this subject is Galen. He died about 200 A.D., just two centuries before the entombment of the Romans or Romanised Britons whose sarcophagi were discovered on the site of our present school buildings. In the latter half of the second century of our era he was the chief physician in Rome. It is not known whether the Emperor Severus visited London in his British expedition, but if he did it is not impossible that there were among his officers patients of Galen who, walking in the country beyond Walbrook, may have considered the strategic advantages of Holborn-hill and Pentonville from the site of our hospital. He was a native of Pergamos in Asia Minor and of course wrote in Greek. His father was learned in mathematics, architecture, and astronomy,[3] and besides giving him much good advice and a taste for learning placed him under the tuition of several learned men of the chief philosophic schools of the time. After this course of study a dream[4] led his father to decide that Galen should be a physician and he studied medicine first at Pergamos and afterwards at Smyrna, Corinth, and Alexandria. In the year 164, when he was thirty-four years of age, he settled in Rome and soon became famous as a physician there. For more than thirteen centuries after his death his writings were the chief authority on medicine, and he was quoted in almost every medical book, whether Christian or Arabian. Subtlety of division and definition and argument are characteristics of his writings, and he never spares words in the discussion of his subject; but his is the prolixity of enthusiasm and of prolonged thought on every aspect of medicine. He is learned, exhaustive, indefatigable. He wrote six treatises, including eighteen books on the pulse. A short treatise on the pulse which he wrote for students gives a summary of his method. First, he says, learn the natural pulse, then appreciate swiftness and slowness, hardness and softness of the coats of the artery, then notice the intervals, observe equality and inequality and varieties of inequality. He then discusses the differences between the pulses of men and women, old and young, with the effects of sleep, of baths, of wine, of food, of mental emotions, and of pain, concluding with a description of the pulse in various diseases. Galen proved by careful experiment that the arteries contain blood and not merely air or spirit, as some of his predecessors had maintained, pointing to their emptiness in the dead body. Nevertheless, when he felt the pulse he thought that the motion was that of the vital spirit proceeding from the heart through the body. Therefore he regarded the pulse as an important indication of the condition and prospects of the patient. Though this theory of its nature had no basis in fact his observations were often exact and we can agree with many of his results. He gave all the consideration he could to the pulse and the physicians, his disciples, for many succeeding centuries estimated its qualities and drew conclusions from them. Galen felt but did not count the pulse.

A dialogue on statical experiments in the writings of Bishop Nicholas de Cusa, cardinal-priest of St. Peter ad Vincula, who was born in Germany in 1401 and died in 1464, contains the earliest mention of counting the pulse, though the counting was not of the kind we use. The Cardinal was a mathematician with a commendable taste for weighing and measuring. The dialogue is between an orator and a common person. The uneducated person says:[5] "Do you not think that if you were to allow water to flow out of the narrow aperture of a water-clock into a basin while you counted an hundred beats of the pulse of a healthy youth and were to do the same with a sick youth that different weights of water would fall through?" The orator has no doubt of it and the uneducated man goes on: "The weight therefore of water that flows out in relation to the differences of pulses in the youth, in the old man, in the healthy, and the sick ought necessarily to lead to a truer knowledge of the disease, one weight being proper to one infirmity and another weight to another." Everyone who has read at all in Demosthenes will remember the clepsydra or water-clock which marked the length of time for which he was to speak and which was stopped in its running while documents were being read. Galen in the fifth chapter of his book, "De cujusque animi peccatorum cognitione atque medela," gives a full account of the clepsydra and how to make, graduate, and use it. The glass vessel used at present in the operating theatre for irrigating parts of the body during surgical operations is a contrivance closely resembling a water-clock.

Cardinal de Cusa's works were printed at Bâle in 1565. On Nov. 5th, 1581, Galileo, afterwards so famous as an astronomer, entered at the University of Pisa as a student of medicine. His father became rather anxious about his progress, for he spent much time on mathematical studies which took him away from medicine. The wasted time of Galileo led to great results in astronomy just as the time which was taken from medicine by three students of this school, Thomas Young, Robert Bridges, and Edward Granville Browne, led to the undulatory theory of light, to the elucidation of hieroglyphics, to fine verse and to profound Persian scholarship. In Galileo's time as at the present day the greatest ornament of Pisa was its noble cathedral with the graceful leaning tower near one end and the beautiful baptistery standing a little way from the other. Engravings and photographs cannot give the wonderful combination of the effects of colour and form which its exterior presents. In the interior the lofty columns and round arches of its nave and its graceful triforium are no less admirable. It is pleasant to connect so glorious a building with the art of medicine. Galileo watched the swing of the great lamp of the cathedral[6] and noticed, as he thought, that its vibrations, whether great or small, were at equal intervals. He tested this by his own pulse, using it as a measure of time, and was thus led to the discovery of the isochronism of the pendulum. This discovery led to the construction and use of an instrument, long since forgotten, called a "pulsilogy." Sanctorius, a professor of medicine at Padua, claims it as his invention in his "Methodi vitandorum errorum omnium qui in arte medica contingunt,"[7] published at Venice in 1603, and gives a fuller account of it with a figure in his commentary on Avicenna, published at Venice in 1626.[8] The pulsilogy consisted of a scale of inches and of a cord with a moveable weight marked with a transverse line. The number of beats of the pulse corresponding to a given length was calculated by direct experiment, depending on the then recently established doctrine of the isochronism of the pendulum. Thus Sanctorius would speak, not of a pulse of sixty, but of a pulse of so many inches.

Another century passed after the invention of his pulsilogy before the pulse came to be counted as we count it at the present day. Sir John Floyer, a most observing physician, also remembered for books on cold bathing and asthma, published in 1707 "The Physician's Pulse Watch." After a dedication to Queen Anne the preface gives an account of the author's invention. "I have for many years tried pulses by the minute on common watches and pendulum clocks when I was among my patients; after some time I met with the common sea minute glass, which I used for my cold bathing, and by that I made most of my experiments; but because that was not portable I caused a pulse-watch to be made which run sixty seconds, and placed it in a box to be more easily carried, and by this I now feel pulses." When you know that the grandfather of a member of the present staff of this hospital was born within ten years of the publication of Sir John Floyer's book you will realise how recent is the practice of counting the pulse by a second hand on a watch. I shall not trouble you with a history of the numerous instruments for registering the pulse. In "La Circulation et le Pouls" of Dr. Ozanam you will find a full discussion of sphygmographs up to 1886 and in the latest editions of physiological manuals a continuation to the present day. Such methods are of use for graphic purposes in the laboratory, but at the bedside the finger trained to a learned touch must be our instrument and is less liable to error than any mechanical contrivance yet invented.

You have already been taught how to feel the pulse so I will only remind you to exercise some care in finding the artery, to keep your finger upon it throughout your observation, to exercise equal pressure, to count the pulse more than once, to compress the artery lightly first and then more firmly, and finally to make a rule of feeling the pulse in both wrists for purpose of comparison. Study your own pulse and several normal pulses and consider their character as well as their rate. I have had printed a list of eight varieties of pulse which are to be observed in the medical wards this day and which you can go and feel at any proper time.

Slow: Seaman, aged thirty-one years. Luke: 10. (28 beats in a minute.)
Fast: Girl, aged sixteen years. Faith: 2. (120 beats in a minute.)
Feeble: Boy, aged ten years. Mark: 15. Boy, aged eleven years. Mark: 14. Man, aged forty-three years. Mark: 17.
Dicrotic (at times): Man, aged forty-three years (with enteric fever). Rabere: 4.
Of unequal beat: Boy, aged fourteen years (with mitral regurgitation). Mark: 16.
Of aortic regurgitation (water-hammer pulse): Man, aged fifty-four years. Matthew: 18
Artery hard: Man, aged forty-eight years (gout). Mark: 18.
High tension: Man, aged fifty-two years (renal disease). Luke: 24.

The slow pulse of 28 is remarkably distinct and there do not seem to me to be any beats which do not reach the wrist as there sometimes are in such slow pulses. You may easily find many other examples of swift pulse besides the girl aged sixteen in the list. Look at the temperature charts over the beds and satisfy yourselves that a raised temperature is accompanied by a rapid pulse. Two of the feeble pulses are in boys recovering from acute illnesses, and the third is a result of long-continuing wasting disease. Make yourselves familiar with the dicrotism so frequent in the pulse of enteric fever, with the inequality of beat of the pulse of mitral regurgitation and with the peculiar shock of the pulse of aortic regurgitation. You may, I think, satisfy yourselves that the artery itself is hard in the man with gout. This is an observation in which a mistake is often made. I have many times found by dissecting it out post mortem that a hardness which seemed a property of the wall of the artery was really a result of the blood stream, the artery being free from thickening or calcification.

Take early opportunities of observing in the wards some other pulses of which there do not chance to be typical examples to-day—the pulse easily altered by slight excitement so often to be seen in exophthalmic goitre and in the people we call nervous; the pulse of unequal groups common in tuberculous meningitis; the bounding pulse of pneumonia and that of some cases of cerebral hæmorrhage; the pulse influenced from day to day by drugs such as digitalis. Of all these you will soon come across examples. Note the difficulty of being quite sure that the pulse has stopped when you have been feeling it for a period of time with increasing difficulty. However marked the characteristics of the pulse may be do not hasten to a diagnosis from that observation alone. The character of the pulse will sometimes tell you whether an abdominal pain is due to the recent perforation of a gastric ulcer or to a general peritonitis. Its regularity and normal beat will tell you in a few rare cases that a cardiac murmur is produced at the pulmonary and not at the aortic valves.

The state of the pulse is an important aid to diagnosis in all cases; it is the guide to immediate treatment in some; and in many others it is one of the chief prognostic indications. Dr. Ewart in his interesting and useful book, "How to Feel the Pulse and What to Feel in It," mentions seventy-two terms formerly applied to as many pulses. This method of elaborate nomenclature of the pulse begins with Galen and may be dismissed with the remark of Heberden: "Such minute distinctions of the several pulses, if they do not exist chiefly in the imagination, at least have little place in the knowledge and cure of diseases."[9] My advice to you is not so much to ask what a variety of pulse which you may feel is called as what does it mean and what is its relation to the case in which you discover it. It was a conversation on the pulse with Dr. William Ogle, a very learned physician and editor of Aristotle, which suggested to me the subject of this lecture. It is not intended to be exhaustive or to do more than make the beginning of the study of the pulse interesting to you. I may fitly end it with Galen's first words in his short treatise for students: "Οσα τοῖς εἰσαγομένοις, χρήσιμον ἐπίστασθαι περὶ σφυγμῶν, ἐνταῦθα λεχθήσεται (What is most useful to beginners to know about the pulse I have set forth here).

THE OUTBREAK OF ENTERIC FEVER AT CLIFTON.[1]

BY D. S. DAVIES, M.D. LOND., D.P.H. CANTAB.,
MEDICAL OFFICER OF HEALTH OF BRISTOL.

[THE epidemic of enteric fever at Clifton caused by sewage contamination of milk and already mentioned in the columns of THE LANCET forms the subject of a valuable and exhaustive report by Dr. D. S. Davies, medical officer of health of Bristol. The report, moreover, contains a chart (reproduced herewith in fac-simile) showing the occurrence of cases on the various milk rounds. In the report the infected supply is referred to as X and names are for obvious reasons omitted. Dr. Davies says:]

It is a matter for congratulation that in my first report to the new Health Committee I am able to deal with a rapidly declining epidemic the exciting cause of which has been ascertained and removed. Thus during the past three weeks the notification returns for Clifton have fallen from 100 to 60 and again to 19. As the third week from the stoppage of the infected supply is now just completed it is reasonable to forecast that the diminution will be fully maintained. In my report to the Sanitary Committee on Oct. 28th I explained the nature of the epidemic and showed how the facts already ascertained, hurriedly but with minute care, pointed to a source of contamination from one particular farm. Further investigation has proved our original conclusions to be absolutely correct and I have nothing to withdraw from my report of that date. But the accumulation of evidence has thrown much fresh light on some points which were then obscure, and I will endeavour to explain as shortly as possible the main channels of diffusion of the infected milk. One farm only (X) supplied infected milk, but it found its way on to three milkman's rounds in the following manner:—

1. The milk from the infected farm X was consigned for delivery to the distributor in Bristol, by whose man it was met at the Suspension Bridge and distributed direct from the churn to customers without going to any local dairy. Any milk not used on the round was returned, however, to the branch dairy and sold to casual customers. This supply served during the holiday month of August and up to Sept. 26th, when the schools reopened, two districts—(*a*) the high level district, bounded on the east by College-road and on the south by Gloucester-road, and (*b*) the low level district, extending from the Mall to Grenville-place, Cumberland Basin, on the south, and as far as Bellevue on the east. On the re-assembling of the schools at the end of September, however, this supply was confined to the high level district. Some of the earliest cases developing at the beginning of October showed themselves on the low level

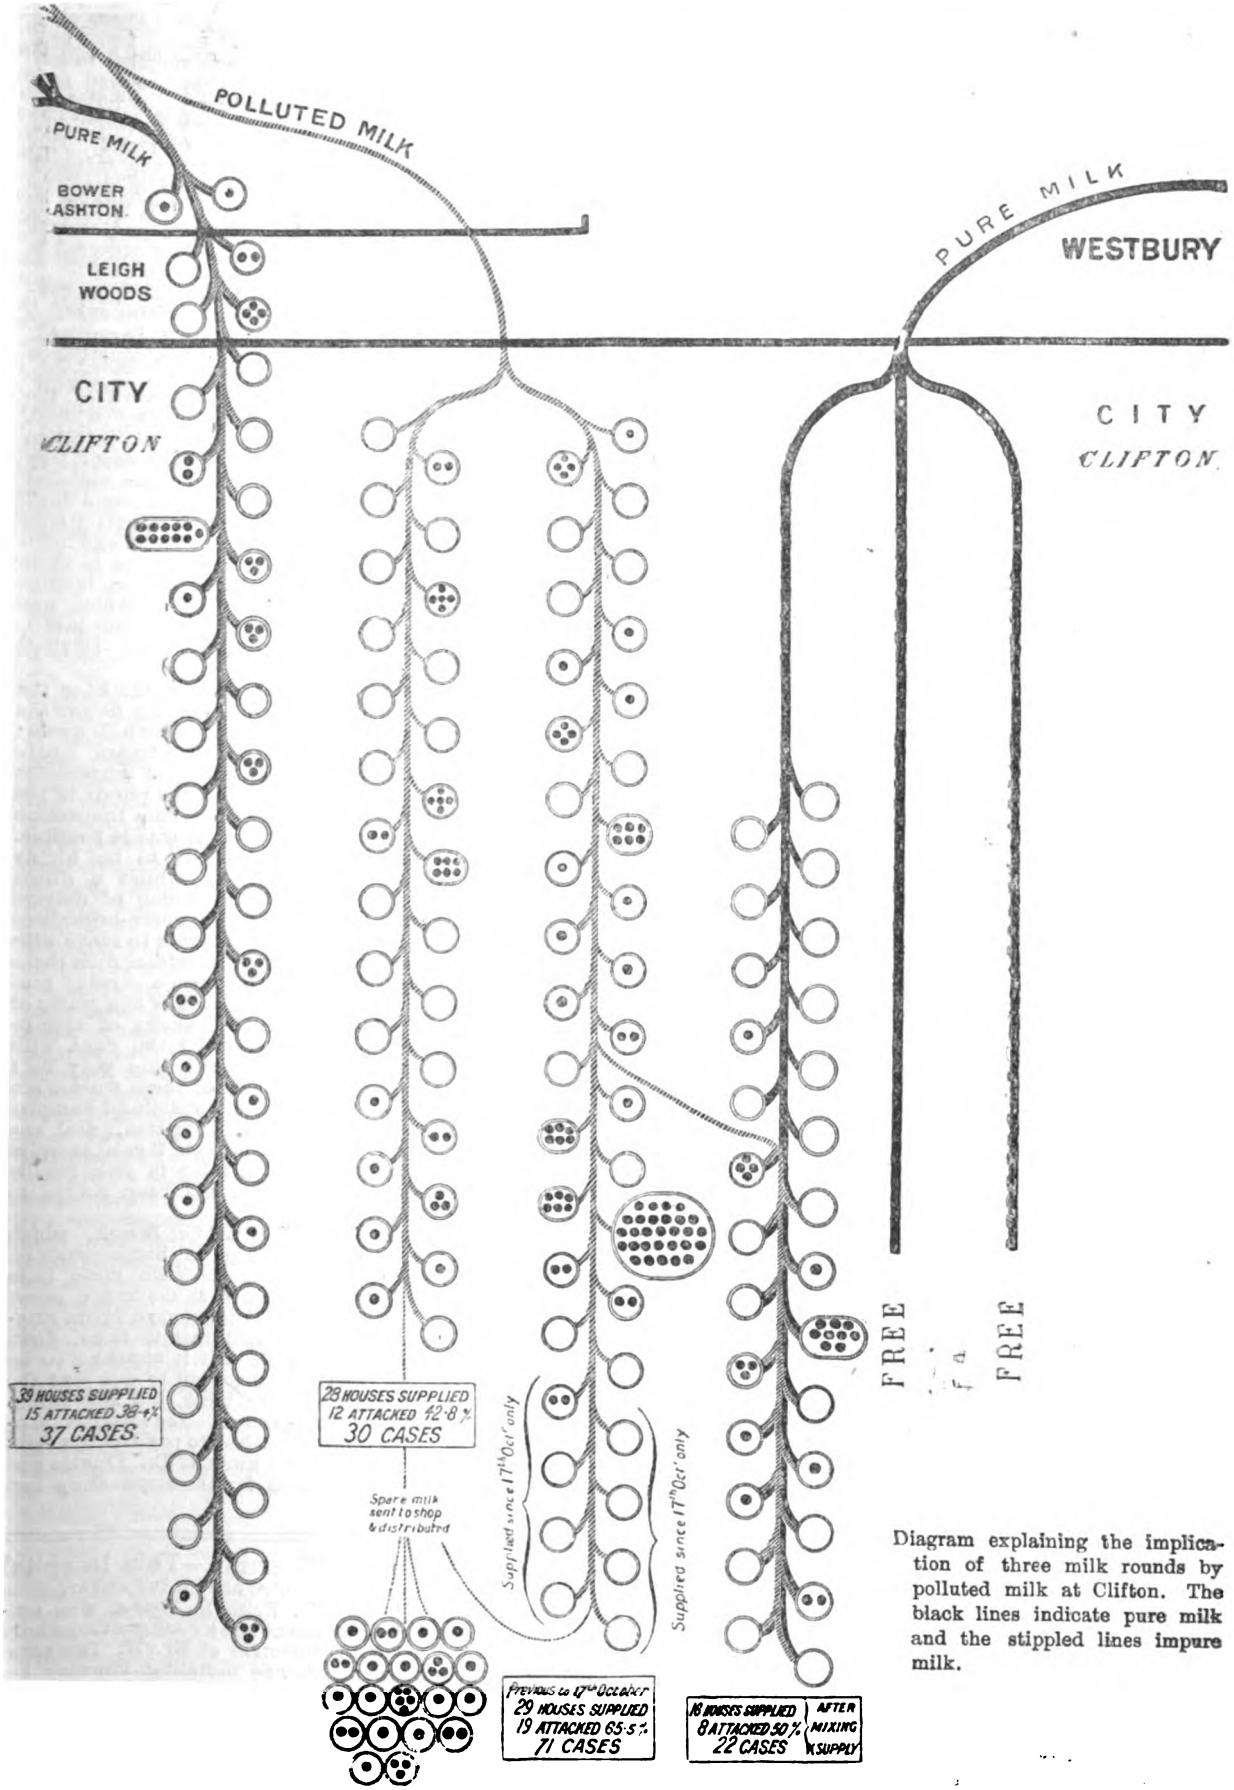

Diagram explaining the implication of three milk rounds by polluted milk at Clifton. The black lines indicate pure milk and the stippled lines impure milk.

Digitized by Google

round, and many early cases also occurred on the high level round, but the incidence here was mainly in the second week of October. On the high level round 29 houses were supplied, 19 were attacked, and 71 cases resulted—a ratio of attacks to houses of 65·5 per cent. On the low level round 28 houses were supplied, 12 were attacked and 30 cases resulted—a ratio of 42·8 per cent. Taken together, 57 houses were supplied, 31 were attacked, and 104 cases resulted—a ratio of 54·8 per cent., or about two cases per house.

2. A milkman started with a pure milk-supply from Ashton, but at Bower Ashton he received a supplementary supply from X (the farm alluded to in the first section) consigned to Clifton, after receiving which he supplied milk to Bower Ashton, two cases of typhoid fever resulting, then proceeding to Leigh Woods, where six more cases appeared in two houses supplied, and then entered Clifton. In the course of his Clifton round the following resulted: 39 houses were supplied, 15 were attacked; ratio of attacks to houses 38·4 per cent.; the total number of cases was 37, or not quite one case per house. In this case a large quantity of good milk was polluted with a comparatively small quantity of infected milk and it will be noted that the attack rate upon houses supplied was smaller and the number of cases per house less. In one school, however, no fewer than 13 cases resulted and two were fatal. I may add that this purveyor had no right to purchase the X milk from the man who was forbiden to sell it. (The report then stated that very great difficulty arose in consequence of statements made to the medical officers' department which failed to give any explanation of the Ashton and Leigh Woods cases. The facts were discovered by a house-to-house visitation and subsequently the whole transaction was explained.)

3. The third and last implicated supply came originally from a farm at Westbury, to which no suspicion attaches, and this furnishes one of the most interesting features of the whole epidemic. The method of procedure adopted in working out the epidemic is this. As soon as suspicion attaches to a farm this is inspected, lists of the customers on the various rounds are obtained, the milkmen on implicated rounds are called to give evidence, the routes of each round are mapped out, and the lists and maps compared with the fever case-books compiled from the inquiries on notified cases. The milk from the Westbury farm is brought into Bristol on three rounds. Two of these rounds were found to be entirely innocent of cases, and the third round was (with the exception of the single case of a servant in one house, situated near the dairy where the returned infected milk went, and from which occasional supplies were possibly obtained) also quite innocent of cases up to a certain point, but beyond this point cases began to occur with marked frequency. These facts went a long way towards exonerating the farm itself as a source of infection. On comparing the mapped-out routes it was observed that at the very corner where this change from freedom to infection occurred this milk round crossed that of the X supply (previously referred to), and we were prepared to receive the admission that at this point, on occasions when the milkman found the demands of one large college house had shortened his supply, he was in the habit of buying a supplementary supply from the other who carried the infected X milk. After this cases commenced at the very next house supplied and recurred with considerable frequency throughout the entire route. The following are the results obtained: Before adding the infected milk 11 houses were supplied, 1 house was attacked, or 9 per cent.; 1 case resulted. After adding the infected milk 16 houses were supplied, 8 were attacked, or 50 per cent.; 22 cases resulted.

The explanation of this implication, which for some time seemed obscure, settles the question of causation and may silence some critics who, failing to trace from their imperfect knowledge any possible channel of infection, have traversed my statements while they have uniformly neglected the courtesy of asking me if I have any explanation. All the persons concerned have admitted before witnesses the accuracy of the facts I here adduce. In the aggregate up to Sunday, Nov. 14th, 1897, we find:—

Total houses attacked.	Houses.	Cases.
Houses attacked on regular rounds	55	163
Houses attacked obtaining casual supplies from the branch to which infected milk was returned ...	20	32
Houses attacked obtaining milk from dairymen not known to obtain infected supplies (no multiple cases in any such house)	13	13
	88	208

I am thus able to account satisfactorily for 195 out of a total of 208, or 93·7 per cent. of the total cases; and when it is remembered that the infected milk was supplied to one retail shop round which a cluster of cases has occurred and to one refreshment room, and when the chances of infection by visiting are taken into account, the percentage of failure, which I hope further inquiry will reduce, is very small. The number of multiple attacks in houses upon the infected supplies is very notable. The largest number in any one house (a schoolhouse) was 29; in others 11, 9, 7, 6, 6, 6, 5, 5, 5, 4, 4, 4, 3, 3, 3, 3, 3, 3, 3, 3 cases occurred, and several double cases in other houses. No multiple cases occurred in any house to which an infected supply cannot be traced.

[Dr. Davies here mentioned that at Clifton College, containing large numbers of boys at susceptible ages, 5 "houses" only were attacked, every one of which received, mixed or unmixed, the infected milk. Each circumstance of the attacks was satisfactorily explained, and it became possible to advise with confidence that the work of the school should continue without interruption and without fear of further infection. Several instances of infection under special conditions were also quoted. In one case a lady attacked was the only one in the house who drank unboiled milk. In another case a child of nine years of age on a day's visit to Clifton drank some of the unboiled infected milk at a restaurant and developed enteric fever at the end of a week (the incubation period in milk typhoid may be as short as five days). The infected milk was supplied to an institution containing sixty-three persons, not one of whom was attacked, in consequence, no doubt, of the milk being invariably scalded in a steam-jacketed cylinder. Dr. Davies's report then continued:]

I have already pointed out to the Sanitary Committee the conditions found to exist at the farm. I now lay before the committee the city analyst's report, from which I quote: "Oct. 30th, 1897. X Farm Pump and Stream above X Farm.—There is a remarkable closeness of agreement between these waters which suggests that the pump is not supplied from a spring but from the stream. Your inspection of the locality will have determined whether this is possible. The analytical results prove these samples to be highly charged with putrescent organic matter, whilst a direct microscopic examination, without the assistance of culture processes, shows them to be swarming with micro-organisms in great variety. Here also it is not possible to state with certainty whether part of the organic filth contained in these waters is or is not of sewage origin. From a careful consideration of the data and from a knowledge of the water of the locality I think there are distinct indications of sewage pollution, but the evidence, as is generally the case with stream waters, is not conclusive. However this may be I have no hesitation in saying that none of these waters are fit to be used for dairy work. I have also examined samples of milk, one received from X farm on 26th inst., and one on the 28th inst. Though in some respects these samples differ from average milk there is nothing in the results to justify the assumption that water has been added to either."

[The "stream above X farm" is Ashton Brook, which flows through Long Ashton, a village in Somersetshire, extending for a mile or more along the main road from Bristol to Weston. The brook is utilised as the main sewer of the village. Dr. Davies found that the sewage from fifty-nine houses is discharged into it and that it then flows directly through X farm. He adds that it appears to be the obvious duty of the rural district council to prevent the continuance of this pollution of the brook, the dangerous nature of which had been amply shown. The Health Committee of the Bristol Corporation resolved to pay for the milk destroyed to prevent infection and awarded Dr. Davies and his staff a cordial vote of thanks for the steps they had taken.]

HUNTINGDON COUNTY HOSPITAL.—This hospital has lately been thoroughly renovated and so far enlarged as to provide forty-two beds. Mr. Keith D. Young was consulted by the Board of Management and his suggestions have been carried out under the direction of Mr. E. Borissow, architect, of Huntingdon. A new operating theatre has been built, floored with terrazzo and lined throughout with opalite. A mortuary chapel, the gift of one of the Governors, is being built. The President of the hospital is the Earl of Sandwich, and the Honorary Secretary is the Archdeacon of Huntingdon.

REMARKS

ON THE TREATMENT OF ACROMEGALY BY THE EXTRACTS OF THYROID AND PITUITARY GLANDS SIMULTANEOUSLY.

BY H. D. ROLLESTON, M.D. CANTAB., F.R.C.P. LOND.,
SENIOR ASSISTANT PHYSICIAN AND LECTURER ON PATHOLOGY AT ST. GEORGE'S HOSPITAL.

IN THE LANCET of April 25th, 1896, p. 1137, I recorded the unsuccessful treatment of a case of acromegaly by pituitary gland substance. In some remarks which followed on the relation between the changes observed in the pituitary body (generally simple enlargement, cystic change, or more rarely sarcoma) and this disease it was pointed out that the internal secretion of the gland might theoretically be modified in three ways—viz., (*a*) by suppression, (*b*) by hypersecretion, or (*c*) by perversion of its composition. Suppression of secretion alone was not likely to account for the disease inasmuch as on that hypothesis the administration of pituitary extract should relieve the symptoms, whereas this therapeutic effect had not been definitely established. Hypersecretion again was improbable since the administration of the pituitary extract had not been shown to accentuate the symptoms. With regard to the possibility that the nature of the secretion was altered and that this perversion of its composition accounted for the changes characteristic of acromegaly the following suggestion was put forward: "That owing to alteration in the secretion of the pituitary the equilibrium between it and the other internal secretions are disturbed. Possibly some toxic body ..... might be thus produced. The thyroid and pituitary glands have been thought to be compensatory (to each other); recently, however, their extracts have been shown to be physiologically antagonistic.[1] Superficially there are some resemblances between acromegaly and myxœdema and it might be thought that acromegaly is the result of a disturbance of the chemico-physiological equilibrium maintained in health by the normal activity of these two glands.[2] Such a consideration suggests that acromegaly might be benefited by giving pituitary and thyroid extracts at the same time."

I have since the publication of this case in THE LANCET been able to test this theoretical consideration as to treatment on two cases of acromegaly. In both cases the pressing symptom of which the patient complained—headache—was relieved by taking twice a day five-grain tabloids of thyroid and of pituitary extract, ten grains of each being taken daily. It is to be added that the skeletal changes remained unaffected and that the amenorrhœa from which both patients had suffered since the onset remained.

CASE 1.—This patient was the woman described in THE LANCET in the communication already referred to. She was thirty-five years of age and had been ailing since 1891, but definite symptoms of acromegaly only dated from 1894, when her hands and feet began to enlarge and her sight began to fail. This was a well-marked case of the disease and the patient had optic atrophy and transient glycosuria. After being treated in the hospital with pituitary extract in February, 1896, she went home and was under the care of Dr. Hollis, of Wellingborough; towards the end of last year, (1896) headache became so intense that she was anxious to undergo any operation that would relieve it. Accordingly she came under my care again at St. George's Hospital. After consultation with my colleague, Mr. Sheild, who had seen her when previously in the hospital, it was decided that no attempt to remove the pituitary body, which from the primary atrophy of the optic nerves was probably much enlarged, was justifiable, but that if the pain continued the skull might be trephined and the subdural space opened with the object of relieving intracranial pressure. She was given the combined thyroid and pituitary extracts and she gradually lost the headache and was able to get up. Her improvement being sustained she went back to her home in March, 1897, with directions to continue the treatment. This advice, however, probably from the extra expense entailed, she did not follow. In June she began to get epileptiform fits with loss of consciousness, and gradually getting weaker she died early on Aug. 16th, on which day Dr. Hollis and I examined her body—fourteen hours after death. The results of this examination were communicated to the Pathological Society of London at the meeting on Nov. 2nd, 1897, but it may be stated here that the pituitary body was greatly enlarged by a soft white growth which invaded the right optic thalamus and microscopically had the structure of a medium sized round celled sarcoma. The thymus was persistent and microscopically showed marked enlargement of the concentric corpuscles of Hassall. The thyroid body was healthy both to the naked eye and microscopically.

This case belongs to the class of acute acromegaly, of which Maximilian Sternberg[3] has collected six examples all accompanied by sarcoma of the pituitary body and running their clinical course rapidly in from three to four years.

CASE 2.—A woman, aged twenty-six years, with symptoms of acromegaly for two and a half years was shown at a meeting of the Medical Society of London on April 12th, 1897. This was a less advanced case than the previous one, presenting no changes in the optic nerves. When she came under observation in October, 1896, she had had severe headache for six weeks. She was taken into the hospital and treated with the combined extracts of thyroid and pituitary glands. She soon lost the headache and subsequently attended as an out-patient until July, 1897, the same treatment being continued. As there was no return of the headache when she was an out-patient its disappearance can hardly be explained as being merely due to rest and improved physical conditions.

In these two cases amelioration of one symptom and that an urgent one—headache—followed the combined administration of thyroid and pituitary gland extracts but the structural changes remained unaltered. The results are too scanty to establish any reliable conclusion as to the value of the treatment but they justify a more extended trial and it is with the object if possible of inducing others who have cases of acromegaly under their care to try this form of treatment that this note is published. One point that specially requires investigation is whether any good effect that may result from the administration of the combined extracts is solely due to the contained thyroid extract or whether the two combined extracts have more effect than the administration of thyroid alone. Pituitary extract has been generally unsuccessful in the treatment of acromegaly while the treatment with thyroid extract has given variable results. Benson,[4] Bruns, and Bramwell[5] record improvement, Bramwell and Ransom[6] report no effect, and Murray[7] mentions temporary improvement which disappeared while the treatment was continued. Under these circumstances it has been thought that any beneficial effects it may have are of a general nature and not due to any specific action on the morbid processes at work in acromegaly. But since thyroid extract has been found to relieve the headache of acromegaly,[8] it is possible that the apparent success of the administration of the combined

[1] Schäfer and Oliver (Journal of Physiology, vol. xviii., p. 277) found that the effect of pituitary extract on blood-pressure was to raise it while the effect of thyroid extract was the reverse. Their "observations would appear to indicate that the opinion which has been freely expressed that the pituitary and thyroid are vicarious in function and which has been based upon the apparent enlargement of the pituitary after thyroidectomy is probably incorrect, seeing that the extracts of the two glands produce entirely contrary physiological effects." On the other hand, it does not follow that because the effects on blood-pressure of these extracts are antagonistic their other physiological actions necessarily follow suit. Dr. Abrahams has kindly called my attention to an interesting paper by Dr. A. Schiff in the Wiener Klinische Wochenschrift of March 25th, 1897, on the influence of thyroid and pituitary glands on metabolism. After referring to the clinical relations and resemblances existing between acromegaly and myxœdema he goes fully into the effects of thyroid and pituitary extracts on metabolism and shows that they resemble each other in increasing the excretion of phosphoric acid.

[2] In connection with this speculation reference may be made to a valuable paper on Acromegaly with Goitre and Exophthalmic Goitre, by Dr. G. E. Murray, in the Edinburgh Medical Journal, February, 1897. He quotes five cases in which exophthalmic goitre and acromegaly have existed together. While inclining to the view that acromegaly is in some way dependent on alteration in the function of the pituitary gland, he says that the coexistence of acromegaly and exophthalmic goitre suggests that there may be some common cause which brings about similar changes in both thyroid and pituitary glands, each in turn producing its attendant symptoms.

extracts was in reality due to the thyroid extract and not to the combination. In this connexion it would be interesting to ascertain what is the effect of thyroid extract on headache other than that of acromegaly; from the fact that it lowers external pressure it might be expected to relieve some forms of headache. In the Report of the Clinical Society of London on Myxœdema[9] occipital headache was present in one-fifth of the cases. On the other hand, excessive doses of the extract give rise among other symptoms to headache.[10]

At the present time the relation of changes in the pituitary gland to acromegaly cannot be considered as entirely understood or definitely settled; it is true that the change in the gland is generally regarded as primary. But it may be that they are both the manifestations of some primary change elsewhere,[11] or, as the occasional association of acromegaly with some or in very rare cases with all the symptoms of exophthalmic goitre on the one hand and the superficial resemblance to myxœdema on the other suggests, the symptoms of the disease may be due to some disturbance of a theoretical equilibrium which in health is maintained between the internal secretions of the thyroid and pituitary glands. In this state of the question the results of more extended therapeutical trial of thyroid extract both alone and in combination with pituitary extract might be of considerable value.

THE LUNGS AS DUST EJECTORS, VIEWED MAINLY FROM A PATHOLOGICAL STANDPOINT.

BY W. AINSLIE HOLLIS, M.D. CANTAB.,
PHYSICIAN TO THE SUSSEX COUNTY HOSPITAL, BRIGHTON.

THE respiratory functions of the human lungs are obvious and any interference with their efficiency in this regard is quickly made known both to the physician and to his patient by the urgency of the symptoms it engenders. It is scarcely surprising to find that an almost equally important service which these organs render our bodies unceasingly, yet unobtrusively, should be relegated by physiologists "to a back seat." I refer to their function as dust ejectors. Dr. E. H. Greenhow[1] was one of the first observers who drew attention to the changes which take place in the lungs of those much exposed to a dusty atmosphere. Subsequently Merkel,[2] Alexander Ross,[3] Mayet,[4] and others studied the subject. The present paper is not, however, written to confirm a proposition already well established that certain dusty occupations will lead to lung disease among the work-people but rather to show that we are all exposed in a modified degree to similar risks from the daily inhalation of dust and that certain well-marked pathological changes in the lungs and elsewhere may not infrequently be traced to a breakdown in the dust-expelling function of the lungs even among those whose surroundings are not excessively dusty.

We are taught by chemists to regard the air as a mixture of certain gases holding a little watery vapour in suspension. Yet I venture to assert that the air my readers are now breathing, the air I have breathed by day and by night for upwards of half a century, is something essentially different from this purely gaseous mixture. Some few years ago I read a paper on what was called "Motes from a Sunbeam." It was, however, a chemico-physical paper treating of air-dust and I should not have here alluded to it had it not been for some experiments in connexion therewith. Clean glass slides such as those used by microscopists were smeared with glycerine and exposed at different elevations to the open air for an hour or more. They were then examined both by the naked eye and microscopically. It was observable that the deposit—for there always was a deposit visible to the eye—varied much with the force and dryness of the wind and with the quarter whence it blew. Sometimes the dust consisted largely of deliquescent crystals of sea-salt brought from the English Channel a couple of miles away if the wind was a strong south-westerly gale. At others siliceous and calcareous particles, or hair, vegetable fibres, and such-like material, were visibly sticking to the glass. It is not, however, with these visible particles suspended for a time in the air that I have now to deal. It is with those minute orts, those fragments of a decaying world, whose very minuteness and want of density if once they are lifted by the wind ensure them a prolonged flotation in the atmosphere. Besides the naked-eye appearances of the slides above described the microscope revealed many other fragments, both organic and inorganic, which it is not necessary to recapitulate. These experiments were undertaken before Koch had shown how we can analyse by cultivations the various aerial bacteria. Where I, however, found visible solid particles in the air at heights of forty and fifty feet above the surface of the ground it may be assumed that thousands of bacilli escaped my notice because their presence was unlooked for. The air we breathe contains, then, besides the gaseous and watery components above mentioned, a variable amount of solid matter suspended in it, partly organic and partly inorganic. Of the organic particles, again, some are living and others are dead. I propose, first, to consider briefly the behaviour of motes whilst suspended in the air and subsequently to show what becomes of them when they have fallen upon the mucous membrane of a bronchial tube or have obtained ingress to the inner recesses of the lungs themselves.

The rate of subsidence of solid particles in still air depends largely upon their possession in a variable degree of three attributes—size, shape, and density. Organic motes are as a rule less dense than those of inorganic origin and consequently the latter sink for the most part more quickly through the air than the others do. The subsidence of motes conveyed onwards by an air current, although modified in special cases by the direction and force of the current, is still mainly controlled by gravitation. In a dusty atmosphere the subsidence of motes is interfered with and it may be indefinitely delayed by wind-gusts. The streams and eddies so produced have a tendency to raise the aerial flotsam to a higher level from the ground than that previously occupied by it. It is the disturbance of organic dust whereby the number of motes in a given volume of air may be temporarily increased that causes a draught in a crowded and ill-ventilated room to be specially dangerous. Along the respiratory tract the subsidence of aerial motes is regulated by similar laws to those in force outside the body. We may rightly conclude that the heavier particles of the road-drift, for example, are when inspired mainly deposited upon the mucosa of the inferior meatus narium of the pedestrian if he is a nose breather. We can obtain ample evidence of this fact as a rule when we clear the nose on a white handkerchief after a dusty walk. This result is probably due rather to the operation of certain physical laws regulating the subsidence of suspended air-motes than it is to any anatomical peculiarities of the nasal cavities as some will have us believe. The air which passes into and out of our lungs under ordinary circumstances does not mingle except by slow diffusion with that filling the upper nares where the complicated convolutions of the olfactory mucosa are found. It follows that the majority of the air-motes will pass along the inferior meatus. We cannot actually see them performing their adventurous voyage through this possibly somewhat constricted passage, but we have indirect anatomical evidence that they really do so. I need only bring to mind that the inferior meatus of the nose is lined with ciliated epithelium in common with the larger air-tubes, whilst this is not the case as regards the olfactory cavities and the pulmonary alveoli.[5] The velocity of the air-current along the bronchi during inspiration must be constantly changing and in the infundibula it will either cease or become greatly diminished. Despite the respiratory movements of the chest and the variable currents they necessarily induce the smallest and lightest motes will have a more favourable chance of passing deeply into the bronchial ramifications along with the inspired air than others. As the smallest and lightest motes are generally both organic

and alive these microbes may occasionally find their way into the alveoli even when other motes are excluded.

When a mote falls upon the mucous membrane of the respiratory tract its subsequent history depends much on its chemical constitution, size, and shape. Metallic and mineral dust as met with in certain dusty occupations include for the most part a large number of sharp-edged or pointed particles admirably adapted to penetrate the mucosa of the tubes. If, for instance, we examine fine iron or copper filings under a microscope many of the minute particles of metal will be found to have assumed the shape of spiral ribbons, some of which are more closely twisted than are others. Yet all are so fashioned as to easily cut into the pulmonary tissues. Coal dust, although composed mainly of smaller particles than the metal filings, is largely made up of pieces with peg-shaped points and cutting edges. Again, mother-of-pearl dust[6] may be almost said to typify a truly penetrative powder, consisting as it does almost entirely of delicate needle-shaped spicules of lime carbonate on some organic, possibly chondrin, base. Finely pulverised flints or other stones, as met with in road drift, in stonemasons' sheds and elsewhere, doubtless possess in many cases considerable cutting capabilities. On the other hand, a very large majority of the air-motes of everyday life are harmless as regards their penetrative ability. These are at once moved onwards, whenever they have fallen on the viscid surface of a bronchial tube, and are eventually ejected into the pharynx by the aid of cilia, supplemented by occasional and forcible expiratory efforts. Having arrived so far on their return journey the motes mixed with mucus are either swallowed or expectorated at the discretion of their possessor. The above sketch represents with reasonable accuracy the progress within the lungs of the myriads of air-motes which every healthy person must have inhaled during an average lifetime. Occasionally it happens that tubercle or other noxious bacilli are introduced together with harmless motes to the bronchial mucosa. So long as the epithelial surface is intact these organisms are swept outwards again by the cilia and are not allowed to obtain a permanent lodgement. If, however, they have succeeded in gaining the infundibula they must be removed with difficulty owing to both the physical and anatomical conditions of their surroundings. This is doubtless one of the modes in which the lungs can become infected by septic bacteria.

The smaller bronchi are proportionally more muscular and contractile than the larger tubes. When one of the former is contracted its lumen is almost obliterated by infoldings of the mucosa. A sudden change of calibre is often rendered necessary to prevent the ingress of solid particles to the alveoli. If, however, a sharply-edged metallic or mineral mote is caught by the contracting tube it is probably forced by the movements of the muscular ring into the parenchyma of the lung. The intrusion of such particles is admittedly well borne by the pulmonary tissues, and it only at times leads to serious and progressive complications. These, when they exist, take the form of patches of sclerosed tissue, each surrounding a bronchiole (Osler). Besides these lesions the arteries are often affected with endarteritis, and the embedded particle is usually surrounded with a zone of pigmented tissue (Woodhead). These appearances are similar, whatever the nature of the inorganic dust inhaled (Zenker). Exclusive of the arterial disease and the pigmentation, to both of which I shall refer subsequently, there are two chief facts regarding the behaviour of the pulmonary tissues when they are invaded by mineral or metallic fragments. First, they bear the intrusion well as a rule; and, secondly, whatever the metal or mineral of which the motes consist, the resultant sclerosis if it takes place is practically identical. These facts undoubtedly point to the pulmonary lesion as the result of a third factor, whose occasional ingress along with the inorganic particles above mentioned is the true cause of the sclerosis. If we consider the possibilities there must be of infection when hundreds of minute pinpoints are being forced in many different directions through the lungs, as is necessarily the case in many instances of pneumokoniosis, we ought not to feel surprise that infective germs are sometimes introduced with them. That this is the true interpretation of the sclerosis, the pigmentation, and the arterial disease will be disclosed in the latter part of this paper.

[6] See a paper by Greenhow: Transactions of the Pathological Society of London, vol. xxi., Organs of Respiration; "Specimen of a Pearl-shell Cutter's Lung."

From what has been already stated we may consider that the lungs have a strong outer line of defence against invasion by air-dust in the branching air-tubes and their moistened lining. When, however, certain mineral or metallic particles are precipitated upon the pulmonary mucosa they are frequently forced into the lungs themselves by the efforts made to dislodge them. Owing to the comparative scarcity of these motes in the dust of ordinary life this accident rarely happens even to dwellers in towns. It is otherwise with small amorphous particles, as smoke-smuts, broken epithelial scales, or the hundred and one oddities which form the air-dust of civilised life. The lungs will grievously fail in their dust-ejecting function when such material is left to choke the finer bronchi. As a rule, I believe, this dust when deposited in the lungs is quickly and thoroughly removed. I even doubt whether many hours' exposure to a smoke-laden London fog will leave an atom of carbon permanently fixed within the meshes of the pulmonary tissues of a healthy man. Some pathologists have assumed that the pigmentation of town-dwellers' lungs is due to the inhalation of an excessively smoky atmosphere. The discoloration may be explained more truthfully otherwise. That the "black-lung" of coal miners[7] is due to the invasion of the pulmonary parenchyma by coal dust is unquestionable; but this intrusion is largely due, as previously pointed out, to the shape of coal particles. Smoke carbon is quite incapable of cutting its way into the mucosa as some coal dust probably can.

When dust has by any means evaded the natural safeguards to its promiscuous introduction within the tissues of the body it loses its individuality if I may so phrase it and its further movements are somewhat difficult to trace. This difficulty is rendered all the greater among the higher vertebrates because, owing to the efficiency of the defences, the intrusion of even the tiniest bacterium is probably challenged and for the most part prevented. Among the Aves the respiratory movements of the lungs are more restricted than they are in mammals, and these organs in birds communicate freely with large air sacs in different parts of the body. The safeguards to prevent the introduction of atmospheric dust or other forms of contamination into this complex respiratory system are apparently trivial and easily evaded—at all events, in some species. For instance, it is not unusual to find entozoa (monostoma mutabile, &c.) in the subocular air cell of the coot, water-hen, goose, and other water-birds.[8] When comparatively large creatures are permitted to live with impunity it is reasonable to suppose that smaller organisms are not rejected. These avian receptacles, notwithstanding their close relationship in many cases to the innermost cavities of the skeleton, must occasionally admit many air-motes. It is difficult to understand how any of the dust when once it has been drawn into these sacs can get back to the open. At all events it seems probable that a far larger proportion of the total amount of captured particles will be retained in these extensive air-chambers of birds than in the lungs of mammals. From what we know of the behaviour of certain motes, as above stated, a percentage of the captured particles will sooner or later become involved in the highly vascular lining membrane and in this manner there will undoubtedly be a risk of blood contamination. When foreign particles get into our blood-vessels they are attacked and devoured, as is well known, by leucocytes. The necessity for depurative measures must be theoretically greater in birds than in mammals, and possibly it is more urgent in water-fowl than in other species of birds if my line of reasoning is sound. We ought therefore to expect in birds' blood a condition of physiological leucocytosis, and water-birds ought to possess this physiological attribute to a greater extent perhaps than land-birds.

In January, 1896, Mr. E Lewys Lloyd kindly undertook to count for me by means of a Thoma-Zeiss hæmocytometer the actual number of red and white corpuscles respectively in given volumes of blood taken from four different species

[7] Black-lung had been recognised as a common result of respiring air laden with carbon-motes many years before Greenhow published his observations. Dr. Gregory, Mr W. T. Cox, and Mr. Couch (Statistical Investigation into the Mortality of the Miners in the District of Lelant, 1859) severally concluded that the discoloration was due to carbon (British and Foreign Medico-Chirurgical Review, vol. ii., 1860, p. 53, and THE LANCET, May 1st, 1869, p. 604, for report of discussion on Greenhow's paper).

of birds. The investigations were made in the laboratory at St. Bartholomew's Hospital and the birds selected were hens, pigeons, larks, and ducks. In describing these enumerations Mr. Lloyd fully upheld the high reputation he has as a painstaking and accurate observer and I here give the average proportions of white to red cells in each of the four species above mentioned as found by actual experiment: in hens the average proportion of white to red cells was 1 : 234, in pigeons nearly 1 : 114, in larks nearly 1 : 166, and in ducks 1 : 97. These results were obtained under identical conditions from several examinations of the blood of two healthy birds in each species. If we take the average proportion of white to the red corpuscles in man to be about 1 in 500 these averages for birds show that a leucocytosis existed in all the tested samples of avian blood; and, furthermore, of birds' blood the highest percentage of white corpuscles to the red existed in the duck, a water bird. These figures as far as they go confirm in a curious manner the suggestion that birds' blood by incurring greater risks of contamination from without owing to the conformation of the respiratory apparatus ought to be provided with a larger proportion of phagocytes than is man's blood for instance. Water birds, again, owing possibly to their dirty habits seem to incur greater risks than do land birds and against these dangers the duck at all events is sufficiently provided by a well-marked physiological leucocytosis.

Pigmentation is a common accompaniment of many chronic diseases of the lungs. It has been found, to take a few examples, not only in cases of anthracosis, but in stone-mason's lung[9]; in the chronic congestion of mitral incompetency[10] and along with tropical abscess of the liver, as in the case hereafter mentioned. The colour of the pigment is usually black; it may, however, be brown, green, or yellow. I shall confine my remarks to the common black variety as the one generally met with even in cases where the rarer coloured pigments predominate. Under a high power the microscope resolves the pigment into minute granules. Many pathologists consider it to be composed of carbon. The transference by wandering cells of granules discharged from other cells or of matter to be converted into granules, "to organs which lead out of the body, where they may be put to secondary uses," appears specially to have been studied by Mr. H. M. Bernard, of the Natural History Museum, South Kensington.[11] Although in some metazoa, the crustacean apus, for instance, the pigment granules of the eye are highly complex bodies, according to the same authority there is no doubt that these granules are mainly excrementitious and are discharged by the wandering cells as waste products. Guanin ($C_5H_5N_5O$) has been found in the granules of some animals. The pigmentary granules found in the lungs of townsmen are doubtless pathological in nature and composed entirely of excrementitious substances. In the following case, which I shall quote at some length, we have indirect evidence (1) that pigment granules were partially digested pus cocci, (2) that they were removed from the blood-vessels by leucocytes, and (3) that the pigment deposited on the middle and outer coats of the pulmonary artery and elsewhere was in every case conveyed in the manner above stated from the blood stream during life.

A soldier, aged twenty-five years, invalided two months previously from India for "ague," was admitted to the Sussex County Hospital in February, 1896. He was then suffering from obscure symptoms suggestive of hepatic abscess. An exploratory puncture, although it showed the presence of a few dead leucocytes, did not localise an abscess cavity so definitely as to justify further operative measures. About a fortnight afterwards he died. At the necropsy the right pulmonary artery was, as regards its larger and medium branches, distended with thrombi, causing typical wedge-shaped areas of consolidation. Some of the infarcts were breaking down centrally into pus. A large abscess, with almost cartilaginous walls, about the size of an orange, was found near to the anterior surface of the right lobe of the liver. No amœbæ coli were found in its contents under the microscope, only pus cells and broken-down tissue. Pus cocci were seen on a cover-glass preparation stained with methylene blue. On inoculating culture tubes with pus, cultures were obtained, but the nature of the organism was not determined. There was no evidence of dysentery in the four inches of sigmoid flexure examined. The above extracts are from the notes of Dr. Arthur Stanley. Upon subsequently making some sections from a thrombosed patch in the lung I noted smaller branches of the pulmonary artery mapped out by dense lines of black pigment, mostly in the outer coats of the vessels. At the angles formed by the insertion of a branch into a larger vessel the pigment was mostly in evidence. Owing to the thrombosed condition of the vessels it was easy to trace the branches of the pulmonary artery. In addition to the walls of the artery pigment was found to a small extent on the pavement cells lining the alveoli, and there were a few scattered granules elsewhere among the pulmonary tissues, possibly along lymph channels. The largest amount by far, however, was heaped around the blood-vessel in the manner described, some of the smaller vessels being apparently changed into blackened tubes. If the black patches were examined with a high power it was easy to resolve them into aggregations of granules for the most part contained within the nuclei of small oval cells, others, although preserving in the aggregate the oval shape, were undoubtedly without a cell-covering. Having stated so much as regards the topographical distribution of the pigment I shall next discuss its probable origin in the case under consideration.

In the above case we have proofs of the finding of pus cocci in the contents of the hepatic abscess shortly after death, an abscess from which we have clinical evidence that the patient had suffered for some long period. At the time of death and shortly before that event we have strong presumptive evidence in the thrombi within the walls of the pulmonary artery that some of these cocci, this living organic dust in other words, had made its way into the blood-vessel. If this happened during the last few days of life—and we can scarcely suppose the thrombi to have lasted for longer—the condition of the abscess walls and the patient's clinical history both confirm the opinion that the hepatic abscess was of older date than the blood-clots. It is highly probable, this being so, that cocci may have escaped into the pulmonary artery in small numbers before the final catastrophe brought about the thrombosis, and that they were seized upon and destroyed by leucocytes ere much harm was done. Both pathology and comparative physiology render it probable, as I have elsewhere shown,[12] that phagocytes after a meal of this kind often seek to free the blood from their presence as soon as may be by passing out of the blood-vessels into the peri-arterial lymph spaces.[13] In the lungs, owing to the substitution of oxygen for the carbon peroxide of the hæmoglobin, the activity and energy of all intervascular changes are accentuated generally and that of protoplasm in particular, and we ought to look for and expect evidences of these changes in pulmonary pathology. The present case furnishes conclusive information on these points if it is rightly construed. The lines of pigment which map out the branches of the pulmonary artery represent the "dumping ground" of half-awakened leucocytes poisoned by their meal upon streptococci pyogenes. That this is no fanciful explanation of these pigmentary deposits there is evidence in the clots themselves, for I have found several leucocytes filled with granules embedded therein, caught and retained in the firmly clotted blood.

We may conclude therefore with a reasonable assurance that our conclusion is true that pigment granules in the lung substance represent in many cases partially burnt or in other words digested dust removed from the pulmonary vessels by phagocytes; and, furthermore, that there is no satisfactory evidence in support of the conjecture that the pigment is ever caused by inhalation of smoke-carbon suspended in the air. The latter particles are probably always swept away by cilia along with the mucus coating the air passages. If we examine the small masses of black pigment so commonly found in the expectoration of a townsman after an influenzal catarrh they will be found to consist apparently of two varieties—namely, of granules contained in oval sacs many of which average 0·001″ long diameter and of granules not surrounded by a cell wall. Sometimes it may happen that the free granules have escaped from a sac

through rupture of the walls, but there is no evidence of this accident in many cases. With the exception of a difference in size, to be accounted for by some general shrinkage in the microscopic sections, a comparison of the pigment cells in sputum with others in the pulmonary tissues shows a resemblance between them which I believe implies an identity of origin. In other words we have here unfolded to our view a second line of defence in the lungs, whereby even after the entrance of pernicious organic dust into the blood[14] the freshly stimulated phagocytes in the smaller branches of the pulmonary system of vessels at once attempt its oxidation and removal.

The difference in size between the granule-bearing cell and the average leucocyte may be explained as follows: the pigmented cell is a leucocyte surfeited with the plethora of an indigestible meal. These large cells are found mostly outside the blood-vessels either in the pulmonary tissues or in the sputa of a patient. They then represent cells whose active locomotion is over or is largely replaced by internal molecular movements, constituting digestion and tending to the growth or enlargement of the cell. It is not difficult in many cases to pick out pigment cells in various stages of growth from the size of an average leucocyte onwards. In the higher vertebrates the extra-vascular pigmented cell must be a comparative rarity, to be met with only in cases of urgency when the blood-motes are from sheer numbers in danger of gaining an ascendancy over the rest of the body. Otherwise much organic dust in the pulmonary system of blood vessels, after being devoured and partially consumed by phagocytes, is conveyed onwards by them to the left auricle. Thence the blood current makes a twist upon itself before reaching the aortic ostium by passing sharply round the free edge of the aortic cusp of the mitral valve. This mitral curtain corresponds to the single valve, guarding the auricular opening in reptiles, and is most developed in birds.[15] Conformably to its ancient evolutionary pedigree we might expect this flap to be affected at an early period, whenever an excess of half-poisoned leucocytes passed around it. And so I believe it really is, although I have no statistics bearing upon this statement; my experience certainly favours the supposition that atheroma more frequently affects this cusp than it does other parts of the endocardium. In tracing the subsequent progress of the surfeited phagocytes along the blood-vessels we should have to recapitulate the arguments I have elsewhere given in favour of the dust origin of aortic atheroma. This is unnecessary. I shall content myself with pointing out that the partial failure of the dust-restraining function of the lungs offers a simple and more satisfactory explanation of the etiology of aortic atheroma than any other that I have yet seen.

A BRIEF ACCOUNT OF TROPICAL ABSCESS OF THE LIVER.

BY C. W. WINDSOR, M.A., M.D. CANTAB.

IN this article I have endeavoured to bring out the striking connexion of dysentery with hepatic abscess and also to try to prove some relation between these two affections and the amœba coli. My own experience has been derived from the study of cases during the last two and a half years at the *Dreadnought* Seamen's Hospital, where perhaps more cases of abscess of liver and dysentery are met with than elsewhere in England. A brief *résumé* of the cases appears at the end.

Symptoms.—The onset of the symptoms of tropical abscess of the liver is commonly gradual and insidious and the patient may only seek advice when the abscess is fully developed. In many instances everything points to the presence of an abscess but there is no one single symptom or physical sign which is absolutely diagnostic of the condition. Early in the case the patient may complain of lassitude, weakness, and feeling of general ill-health and of loss of appetite and impaired digestion. A general alteration in the complexion is very often noticed, though when the patient has lived for a long time in tropical climates this change will not be very well marked. This alteration is one of increasing sallowness with a muddy, earthy appearance of the face. The eyes look heavy and there are deep shadows beneath them. There may be attacks of jaundice either transient or permanent, but it is not common to see any of the symptoms of biliary obstruction. The bowels are usually constipated and obstinate vomiting is said by Murchison to be frequent, but in the cases I have seen this has not been present in one; digestion is impaired and the tongue is coated. The first definite sympton is that of pain commonly situated in the right hypochondrium. This may be of two kinds: (*a*) a dull, heavy, aching pain; and (*b*) a sharp, stabbing pain. The former is the more common and usually shows the gradual increase in size and stretching of the liver tissue and integuments. The presence of a pain referred to the tip of the right shoulder is common. The sharp, stabbing pain is probably nearly always due to pleurisy or in rarer cases to perihepatitis. The pleurisy often goes on to the effusion of fluid though only to a moderate extent—*vide* case. This symptom—i.e., pleurisy—is brought about by the extension of the inflammation to the superficial parts of the liver, causing adhesion of the liver to the diaphragm and then implicating the parietal and visceral layers of the pleura. This process may stop short at almost any stage, so that the liver may not be adherent to the diaphragm or the layers of the pleura may not be involved at all, or only the parietal layer, in which latter case the pleural cavity is open. In long-standing cases the liver, diaphragm, and pleura are all firmly matted together, so that perihepatitis to a limited extent—i.e., over the surface of the abscess—is very common, but this is not invariably the case, as sometimes the liver is quite free from the diaphragm and has to be stitched to the edge of the wound before the abscess can be opened. Great stress has been laid on this perihepatitis from the point of view of diagnosis, but I think that the differentiation of friction due to perihepatitis from that due to pleurisy, except in those cases where well-marked friction is heard either low down over an enlarged liver or in the epigastrium, must be almost impossible. The size of the liver is of great importance; there is usually enlargement which may be upwards or downwards or in both directions, the former being common. It must be remembered that any increase of the dulness above the sixth rib may be due to a localised collection of the fluid in the right pleura quite as much as to enlargement of the liver. The increase in the liver depends upon the situation and size of the abscess. The lower border is often felt to be smooth and rounded as if the edge had been rolled under; the contraction of newly-formed fibrous tissue on the under surface (due to perihepatitis) may account for this. There may be bulging of the right side and bulging of the intercostal spaces with perhaps slight increase in measurement; if the left lobe be implicated there will probably be an easily recognised elastic swelling in the epigastrium. The increase in the area of liver dulness may be appreciable behind, usually extending upwards towards the angle of the scapula. There is nearly always tenderness on palpation over the liver, especially on firm pressure in the lower intercostal spaces. A very constant and valuable sign of hepatic abscess is œdema of the skin over the lower ribs, but this is not absolutely diagnostic any more than in a case of empyema. Redness of the skin and fluctuation will be present only when the pus is approaching the surface. There is pyrexia of a remittent or intermittent type; this fever is not as a rule very high, 102° or 103° F. being the common limits. It may show curious remissions, the patient being free from fever for a few days, after which the temperature rises and may take a typical hectic character. In some cases the fever may be slight or even absent, especially in long-standing cases. Actual rigors are not commonly seen except occasionally in the early stages of the disease, but the occurrence of profuse sweatings, especially at night, is considered a characteristic feature; these sweatings are not so frequent as in pyæmic abscesses of the liver. Jaundice has already been mentioned as being rare; Murchison attributes it to a catarrh of the bile ducts. It was only noticed in five cases out of 120 collected by Moorhead. Marked emaciation is very commonly found and, with the sallow cachectic complexion, helps to give the patient a very characteristic appearance. It is only rarely that portal obstruction is brought about by the pressure of a large abscess.

Terminations of a tropical abscess.—It may be diagnosed nd treated surgically. Rupture of the abscess into the general peritoneal cavity may occur, as was the case in four of the fifty-eight cases treated in the Seamen's Hospital during the last twenty-seven years. In the same series ten abscesses perforated the diaphragm, six of these bursting through the lung and four opening into the right pleura. The stomach, transverse colon, and right kidney were perforated once each in the above series. It will be noted that there is no case amongst the fifty-eight just mentioned showing the rupture of an hepatic abscess into the pericardium, so we may fairly presume this mode of termination to be rare, as this series may be taken as representing a record of average cases. Apart from surgical interference it is most common for the abscess to extend upwards and burst through the lung; in the recognition of this condition the expectoration of brick-red pus is most important. The diagnosis of tropical abscess of the liver is not always simple; many features may be present to render the presence of an abscess probable, but an exploration with a syringe and hollow needle is almost always necessary before the diagnosis is settled. Stress will naturally be laid on the question as to whether the patient has lived in the tropics or if he has had dysentery. Empyema has been frequently confused with tropical abscess, but the characteristic red pus ought to prevent error. The diagnosis between tropical abscess and a large subphrenic abscess is almost impossible before operation and even then the distinction is not always clear. Congestion of the liver, cirrhosis, or acute hepatitis may present a little difficulty, but an exploration will put the matter beyond doubt.

Treatment.—We can be very brief on this subject as it rests entirely with the surgeon to say how the abscess shall be evacuated. It is important that operation should be undertaken as soon as the abscess is diagnosed; nothing is gained by delay, it being useless to wait until adhesion of the various structures has taken place with the idea of minimising the risks of the operation. If the layers of the pleura are non-adherent or the liver not attached to the diaphragm these layers must be stitched together and the abscess opened a few days later when adhesion has taken place. It does not concern the physician to decide on the merits of the different operative procedures, but one may perhaps express the preference for resecting a portion of rib and free incision of the liver over the abscess to the plan of aspiration which is frequently recommended. The prognosis in tropical abscess cannot be expressed in very certain language. So much depends upon its early diagnosis and active treatment; under these circumstances the outlook is quite hopeful. But when an abscess has existed some time and then finally bursts into the lung or some abdominal viscus the patient has rather a poor chance and frequently succumbs to exhaustion or to some intercurrent affection, especially dysentery.

Pathology and morbid anatomy.—Most commonly only one tropical abscess is found in the liver, but there may be two or three large ones quite separate or communicating with each other by narrow channels; and in some cases there may be a large number of small abscesses scattered throughout the whole of the organ. When the abscess is single it is far more frequently found in the right lobe and nearer to the upper surface, as shown in Waring's series of 300 cases, in nearly 70 per cent. of which the abscess was in the right lobe and nearer to the convex surface. It is fair to suppose that where one abscess has been successfully treated and the patient recovers that only one abscess was present in the liver, although it has been suggested that other abscesses may have been present but were eventually absorbed but this is far from probable as the effect of the operation would be to stimulate other purulent collections rather than promote their absorption. Waring found that out of 288 cases of tropical abscess 177 were single. At the Seamen's Hospital, Greenwich, between 1870 and 1895, in 25 cases out 44 the abscess was single. At the same hospital during the last two years 7 cases have been recognised, 2 showed multiple abscesses, whilst the remainder were single. So that out of 51 cases 30 showed the presence of only 1 abscess—i.e. nearly 60 per cent. These 30 cases were judged to be single thus: 14 were examined post mortem; 12 recovered after one operation; and 4 burst through the lung and recovered. The remaining 21 cases were composed thus: 13 with multiple small abscesses and 8 with 2 or 3 large abscesses. It is difficult to say why the tropical abscess is usually single, there must be something in the nature of the tropical abscess to account for this fact as other varieties of suppuration in the liver are almost always multiple.

Presuming that the abscess is caused by something travelling to the liver from the ulcerated large intestine, then this material would be disseminated throughout the liver following the distribution of the branches of the portal vein, and why should an abscess form at one place and not be scattered in different parts of the organ? No definite solution can be given. It is probable that a large abscess is formed by the fusion of several small collections of pus. One may say that a lowering of the vitality of the liver tissue at one spot will determine the formation of an abscess there, but this assertion brings one no nearer to answering the question. Those who attribute tropical abscess to acute hepatitis say that the inflammation is most severe at one spot and so goes on to the formation of pus, but this is only pure assumption and based upon the somewhat slender foundation of acute hepatitis, which is itself a little open to doubt. The size of tropical abscess varies between very wide limits, a superficial collection of a few ounces of pus may produce sufficient indications for operation, while in long-standing cases there may be a huge abscess containing as much as three pints of pus which has only produced marked symptoms in its later stages or may even have passed unrecognised until discovered at the necropsy. The abscess cavity is lined with a ragged yellow material presenting a shaggy appearance, or the inner walls of the cavity may be honeycombed, the interstices of which contain pus. This lining membrane consists of necrosed liver tissue, leucocytes and coagulated fibrin. A definite fibrous capsule is very rarely seen, and then in chronic cases only, but there is always a zone of hyperæmic liver tissue surrounding the abscess which merges on the one side into normal hepatic substance and on the other into the shaggy membrane lining the cavity. If the abscess has approached the surface there will be considerable thickening of the peritoneal coat of the liver, and the process may extend still farther involving the diaphragm and layers of the pleura, matting all the layers together into firm fibrous tissue. The pus contained in the abscess is very commonly of a brick-red or anchovy sauce-like colour due to the disintegration and necrosis of the liver tissue accompanied by slow oozing of blood into the abscess. This colour of the pus is very characteristic, although not met with in every case, cases which have been diagnosed as empyema or pleural effusion only being rightly diagnosed as having their origin in the liver by the withdrawal of this reddish coloured pus. It is probable that this colouration of the pus only occurs when the abscess has reached a moderately large size, for in a recent case in the Seamen's Hospital the large abscess had burst into the pleura and was aspirated under the belief that the patient had an empyema. Chocolate-coloured pus was removed, while on examination of the liver at the post-mortem examination three small abscesses about the size of a walnut were found in which the pus was of the ordinary yellow colour. After an abscess has been opened the pus quickly loses this red colour and the draining on the third day is usually of the ordinary colour of pus. On microscopic examination there is a great preponderance of the ordinary granular pus cell staining deeply with logwood. In addition one sees large irregular shaped cells with a large solitary nucleus, sometimes deeply stained with bile. These represent liver cells in various grades of disintegration and necrosis. Red blood corpuscles are in great abundance; cholesterin crystals and fat globules are also seen.

The pus from a true tropical abscess usually shows a complete absence of pyogenic organisms. In several of the cases at the Seamen's Hospital recently attention has been paid to ascertain the truth of this assertion. When a true abscess has been suspected and an exploration puncture is about to be made the skin is thoroughly cleaned and the exploring needle sterilised. The pus withdrawn has been carefully examined with high powers under the microscope and no organisms have been found. In addition to this several culture tubes of blood serum and agar-agar have been inoculated with the pus both on the surface and by stabbing and no effect on the nutrient medium has been produced nor has a growth of staphylococci or other organisms been found. As bearing on this question of the sterility of the pus Case 7 is interesting. At the time of operation no adhesions were found and the peritoneal and pleural cavities were opened and some pus undoubtedly entered. The liver was then stitched to the edges of the wound and the layers of the pleura united. No peritonitis or pleurisy developed

Digitized by Google

and examination of the pus failed to show any pyogenic organisms. Osler expresses the opinion—based upon Councilman and Lafleur's experiments—that the pus of "tropical abscess" (connected with dysentery) is quite free from pyogenic bacteria. On the other hand, Macfadyen holds that in tropical abscesses pyogenic organisms are constantly met with, staphylococcus pyogenes aureus being the commonest, while the staphylococcus albus and streptococcus pyogenes are often found.

This point about the sterility of tropical abscesses is most important. If it can be clearly proved that infective organisms are constantly present and are the essential cause of the suppuration then there will be little reason for differentiating a special class of abscess of liver; that is to say, all hepatic abscesses will be of an infective nature and the only features specially characteristic of the tropical abscess would be its occurrence most frequently in the tropics, its tendency to be single, and finally a curious connexion with dysentery. This latter connexion would be quite easily explained by the entrance of the infective organisms from the lesions in the large intestine into the lymphatics or portal radicles and which would so be carried to the liver. On the other hand, if we admit the conclusions of Councilman and Lafleur, supported somewhat by the observations on our own cases, as being substantially accurate, the pyogenic character of the abscess would be disproved and it would be necessary to find some other cause for the production of tropical abscess.

Admitting that careful examination of the liver pus fails to reveal any septic organisms there is another frequently found constituent of the pus of tropical abscess which it is necessary to recognise and place upon it whatever value it may possess. When examined in the ordinary way, in addition to the ordinary constituents of the pus a certain number of large round bodies considerably larger than white corpuscles are seen containing a number of red blood cells and an indistinct nucleus. The ground work under a low power looks granular, but on focussing a large number of vacuoles are seen. On staining with logwood the nucleus becomes very apparent but the vacuolation is not so distinct. If no other steps be taken in the examination of the pus nothing further will be made out with regard to these round bodies. But if, on the other hand, the pus be kept at a temperature of 100° F. from the time of its removal from the body (either from an exploration or from the fresh drainings from the wound after the abscess has been opened or from the freshly collected sputum in those cases in which the abscess has burst through the lung) and examined upon a warm stage these bodies undergo a most remarkable series of changes. The method that I have adopted is to collect the fresh pus—preferably that of a yellow colour—in a warmed test-tube which is then placed in a vessel containing hot water, the pus will then be kept warm and can be examined on a warm stage almost at one's leisure. The changes about to be described have been observed after the pus has been kept in this manner for twenty-four hours. A very handy and simple warm stage can be made out of a strip of copper 14 in. long and 1 in. wide, the lower edge being bent up at a right angle forming a support for the slide; in the middle of the copper a round hole of about 1 in. diameter is cut through which the light is reflected up from the mirror on to the specimen. At each end of the copper a small spirit lamp suffices to treat the whole length of the copper bar and also the slide resting upon it.

One very important thing to be remembered in the search for amœbæ is the fact that the pus withdrawn at an exploration or that evacuated at the time of operation very frequently contains no amœbæ whether living or dead. At the same time the fact will be recalled that the pus found under these conditions is nearly always of the brick-dust colour. But if the pus is carefully examined on the warm stage amœbæ will almost certainly be found on the second or third day and then as the discharge diminishes and the pus becomes yellower amœbæ may be abundant. It thus appears probable that the amœbæ remain near the spreading border of the abscess and not in the older pus in the central part of the abscess. This has been the case in at least four of the seven cases which have come under my own personal observation. I feel sure that if this fact were fully realised and the adequate precautions taken when searching for the amœbæ many cases which have been declared free from them would show their presence. In the last seven cases out of the series of fifty-seven taken from the Seamen's Hospital, Greenwich, the pus was not examined in two, and out of the remaining five four showed amœbæ, and in two recent cases under the care of Dr. Patrick Manson both showed the presence of amœbæ. In the earlier cases of this series of cases the microscopic examination of the pus was not made. During recent years amœbæ have been frequently found in liver pus, especially by American observers. When examined in the method described the bodies, which in the ordinary examination are round, show most active movements and the greatest variations in shape. These, then, are easily recognised as the amœbæ coli. Owing to the constant movements the size of the amœbæ cannot be stated; but some are large, with a diameter of 60μ; others are smaller, with a diameter of from 25μ to 40μ. Their shape is oval or round in a resting or dead condition, but when actively moving presents great variations. The constant and characteristic feature of these organisms is their capacity for throwing out pseudopodia, it may be in one or in several directions. Under observation a short, thick, blunt-pointed projection appears at the edge of the amœbæ which gradually increases in length by a peculiar flowing movement, the amœbæ itself becoming proportionately smaller. This pseudopodium has precisely the same structure as the main body of the amœbæ. Sometimes it is withdrawn into the body of the amœba or its extremity may become fixed, and the whole body of the organism merges into the pseudopodium again. One characteristic of this throwing out of processes is the power the amœba has of enclosing neighbouring cells or particles. One can often see the inclusion of a red corpuscle thus take place.

The structure of the amœba is difficult to make out clearly owing to its hyaline translucent character. There appears to be a well-defined outer edge although the organism is really a naked mass of protoplasm without a cell membrane. The main body of the amœbæ may be divided into two parts (1) an outer clear investment, the ectosarc; and (2) the inner granular looking endosarc. In the latter numerous small vacuoles are seen, not of regular size but occasionally one is seen considerably larger than the others; nothing has been seen of the nature of a contracting vacuole, in which respect it differs from the ordinary freshwater amœbæ. Situated in the endosarc is the large single nucleus, but this cannot be usually seen in living specimens but in amœbæ killed with a little acetic acid or by cold the nucleus is brought out distinctly on staining with logwood or magenta. In nearly every amœba a variable number of red corpuscles are seen. There may be as many as fifteen or twenty arranged in various ways and their overlapping edges help to give rise to the granular appearance of the endosarc. Sometimes dark masses of pigment are seen and the amœbæ are sometimes stained yellow with bile. It has already been mentioned that in all the amœbæ under my own observation no micro-organisms have been found in living or stained preparations. This is equally true of those found in liver pus or in dysenteric stools, which latter have been swarming with bacteria.

Influence of race.—Tropical abscess of the liver is much more common among Europeans living in the tropics than among the natives, although it is curious to note that the latter class suffers almost equally from dysentery and malaria (Cayley). It is a striking fact that as civilisation in India increases so does the frequency of tropical abscess among the richer and more leisured class of natives. In the series of 57 cases at the Seamen's Hospital, Greenwich, the race was noted thus: British, 38; Germans, 3; Hindoos, 7; Scandinavians, 4; Africans, 3; and Portuguese, 2. With regard to age tropical abscess is very much commoner between the ages of twenty and forty years; thus in the above series of cases 40 of the 57 were between these limits. Tropical abscess is far commoner in men than in women.

[The continuation of this paper, dealing with the connexion between tropical abscess and dysentery, and a set of illustrative cases will appear next week.—ED L.]

THE RETREAT, YORK.—The 101st report of The Retreat, York, a registered hospital for the treatment of mental diseases, states that on June 30th, 1897, there were 156 patients in the institution, 63 men and 93 women, the average number of patients during the year being 156·04 or 1·76 less than during the previous year. With regard to the finances the amount received as board of patients shows a slight increase as compared with the year 1896 and is higher than in any previous year. The nurses' accommodation has been improved.

A CASE OF

HYSTERECTOMY WITH SOME UNUSUAL AND INTERESTING COMPLICATIONS

BY COURTNEY NEDWILL, M.D. R.U.I., M.R.C.S. ENG.,
VISITING SURGEON TO CHRISTCHURCH HOSPITAL, NEW ZEALAND.

ON June 8th of this year I was asked to see an unmarried woman, aged forty years, whose menstrual periods had always been very regular every four weeks. She said that about two and a half years ago she had a sudden attack of very severe pain over the womb which lasted some hours and was attended by faintness, and about three months before I saw her another similar attack with vomiting had occurred. After these attacks she was quite sure that she had no vaginal discharge. The condition of her bowels lately had varied between diarrhœa and constipation. For years she had been troubled with having to pass urine day and night at short intervals. Under an anæsthetic an examination revealed a moderately large tumour of the uterus situated on the left side. When the os uteri was pulled down with a volsella the sound passed in a distance of barely one inch. On the right side was another tumour of larger size but much less resistant to pressure.

On the 11th I opened the abdomen and found no difficulty in withdrawing a cylindrical-shaped fibroid tumour weighing nineteen ounces in which the diminutive uterus was buried. A wire was passed round the cervix and made to include the left ovary and tube. On approaching the right side I found a hæmatomatous-looking tumour which appeared to be so soft that I extended the abdominal incision above the umbilicus so as to enable me to enucleate it with less risk of rupturing it. I then packed it all round with sponges and turned out a large quantity of old blood-clot. The bowel was adherent, but there was not much difficulty in separating it and teasing out the tumour until a pedicle was found and secured at the broad ligament. No ovary or tube was discovered. (I am sending this specimen to Mr. Bland Sutton to ask him to be good enough to tell me what it is and to append his opinion to this report.) The uterine stump was so easily brought outside the abdomen that the serre nœud pins had no strain on them. Everything went on well with a normal temperature till the fourth day, when she began to complain of flatulent distension and great discomfort. A saline draught of sulphate of soda and sulphate of magnesia was given and frequently repeated until fourteen drachms had been used; in addition she had fifteen grains of calomel in three doses of five grains each. Turpentine enemas were also used with both long and short tubes, but neither flatus nor motion was passed. On the sixth day she began to vomit and continued on this and the following day to bring up large quantities of characteristic fæcal matter. Both the vomit and the breath were offensively fæcal to the smell. She had been going on so well up to the fourth day that she was then taking teaspoonfuls of Brand's essence and ounce doses of peptonised milk. Her temperature was now slightly subnormal in the morning with a rise in the evening of only 1° F. I used my utmost endeavours with her to allow me to open the wound to find out the cause of obstruction, but she would not hear of it. After vomiting set in nothing was given by the mouth, and beef enemata were administered. On the eighth day the nurse, on washing out the rectum before giving a nutrient enema, noticed what she thought was a fæcal smell coming from the discharged water, and as the beef-tea injection was not retained she kept it for my inspection as she thought that it looked fæcal in character. This point, however, was soon set at rest, as during the day several large loose motions were passed.

There is nothing further worthy of notice to report in this case. The convalescence was rapid and the bowels afterwards, if showing any tendency to sluggishness, were easily relieved by teaspoonful doses of castor oil. I have never known of a case with fæcal vomiting where the termination was favourable without the obstruction being relieved by operation.

Christchurch, New Zealand.

Note by Mr. BLAND SUTTON. — The blood-containing tumour was an ovarian cyst which had undergone acute axial rotation.

CASE OF OVARIAN CYST WITH UNUSUAL HISTORY.

BY J. B. HELLIER, M.D. LOND., M.R.C.S ENG,
SURGEON TO THE HOSPITAL FOR WOMEN AND CHILDREN AT LEEDS; LECTURER ON DISEASES OF WOMEN AND CHILDREN IN THE YORKSHIRE COLLEGE.

A WOMAN, aged sixty-two years, a widow, mother of two children, was admitted to the Hospital for Women and Children on July 14th, 1897, for ovarian tumour. She passed the menopause at fifty years of age and seemed to have enjoyed very good health till four years ago, when a soft, uniform enlargement of the abdomen was noticed. This did not seriously incommode her till about Christmas, 1896, when the increasing size of the abdomen began to interfere with breathing and she had much pain in the back. But in March, 1897, she was taken very ill and was seen by Mr. J. W. H. Brown and Mr. A. E. Ellison, of Holbeck, who have kindly given me details of the condition in which they found her. She was suffering from pneumonia of the right base and probably also of the left. She was extremely prostrate; her breathing was rapid and shallow, the pulse was very rapid and feeble, the lips and nostrils were covered with herpetic sordes, and the abdomen was enormously distended with fluid, being tense and elastic with well-marked thrill. The urine was not albuminous; the bowels were costive. The patient was unconscious and wandering and seemed at first to be absolutely moribund. Ether and digitalis, &c., were administered, and on March 18th paracentesis was performed in the middle line two inches below the navel. Three and a half gallons of excessively offensive, opaque, greenish brown fluid were slowly evacuated. The abdomen became quite flat except in the hypogastric region, where the cyst wall could be felt like thick leather. After this the patient slowly recovered, but the cyst began to fill again. On admission (July 14th) the patient was found to be a thin, spare, anæmic woman. There was some arcus senilis; the arteries were rather hard. The lips were stained with pigment where the sordes had been. The abdomen measured forty-four inches in circumference and presented the usual signs of a large single cyst rising out of the pelvis to two-thirds of the distance between the navel and the sternum. The flanks were resonant; no solid portion was felt in the tumour. The uterus was mobile and anteverted. Some ill-defined swelling was felt in the right cul-de-sac. The lungs were healthy, the temperature was normal, and the urine also. There was no sign of peritonitis or of septicæmia. In deciding to perform ovariotomy at once I felt anxiety on account of the possible condition of the cyst contents, the probability of adhesions, and the age and weak state of the patient. Ovariotomy was performed on July 21st, 1897. Ether was administered by Dr. Wear. I was assisted by our house surgeon, Mr. Pierson, and Mr. Ellison was present. The tumour was found to consist of one very large cyst with a thick wall. It sprang from the left side and had a pedicle two inches wide. It contained eleven pints of greenish-yellow, opaque fluid which was neither purulent nor offensive. There were extensive adhesions to the abdominal wall, to the omentum, and to the colon. The parietal adhesions were easily broken down; the omental adhesions were ligatured and divided. Those to the colon were separated by careful use of blunt dissector and dissecting forceps. This was a little tedious but was successfully completed. The cyst had no pelvic adhesions. The pedicle was ligatured in two portions. The fundus uteri contained a fibroid of the size of a small orange, but this was not disturbed. The right ovary was embedded in adhesions and seemed somewhat large but not cystic. This also was left untouched. The abdomen was flushed out with sterilised water. There was no serious oozing from the separated surfaces. A glass drainage tube was left in the wound for forty-eight hours. The wound was stitched in three stages and it healed without any suppuration. The temperature was normal from the third day onwards and the patient made a rapid recovery without any bad symptom.

Remarks.—In spite of the tendency of tapping to produce adhesions it holds its place in the treatment of ovarian disease as a measure to be resorted to in cases such as this, when a major operation is for the time being impracticable. Here it saved the patient's life. The most striking feature

Digitized by Google

in the case is the fact that the contents of the cyst were offensive at the time of tapping but not at all so five months later at the time of ovariotomy. The two practitioners who performed the tapping assure me that the fluid drawn off had such a sickening stench that they had to leave the room at frequent intervals to breathe fresh air. At the ovariotomy we noticed no smell whatever, and after some of the fluid had stood two days in warm weather it was still free from unpleasant odour. The cyst wall was rough inside and coated with caseous matter. There were one or two very small secondary cysts in the wall. I have no data to decide whether the pneumonia was secondary to a septic condition of the cyst contents or whether the contents became offensive on account of the pneumonia. But after the evacuation of the fluid the constitution seemed able to deal with any germs that were left and a more satisfactory issue from a desperate condition could hardly be experienced.

Leeds.

AN ANALYSIS OF EIGHTY CONSECUTIVE CASES OF ENTERIC FEVER.

BY ERNEST RINGROSE, L.R.C.P. LOND., M.R.C.S. ENG.

THE 80 cases from which this analysis is made came under my observation at the hospital, Newark-on-Trent, between August, 1891, and November, 1893, during which time two epidemics occurred in the town and district; 73 occurred in the town and 7 were sent in from the outlying districts. As to sex, 52·5 per cent. were males and 47·5 per cent. were females. Between the ages of one year and five years there were 8 cases; between six years and twelve years there were 22 cases; between thirteen years and twenty years there were 27 cases; between twenty-one years and thirty years there were 11 cases; between thirty-one years and forty years there were 8 cases; and between forty-one years and fifty years there were 4 cases. One case only occurred in which the patient had had enteric fever previously—viz., four years before. The initial subjective symptoms were chiefly headache (frontal), vomiting, and pain in the abdomen; in 27·5 per cent. of the cases there was epistaxis.

The maximum temperature, taken in the axilla, was as follows: 109° F., 1 case, fatal; 108°, 1 case, fatal. The temperature ranged from 104° to 106° in 12 cases, 4 of which were fatal; 103° to 105° in 28 cases, 4 of which were fatal; 103° to 104° in 28 cases, 3 of which were fatal; 102° to 103° in 7 cases, none of which were fatal; and 101° to 102° in 3 cases, none of which were fatal. The highest temperature reached during the attack occurred during the first week in 19 cases; during the second week in 28 cases; during the third week in 23 cases; during the fourth week in 6 cases; and during the fifth week in 4 cases. The temperature remained normal at the end of the second week in 1 case; during the third week in 17 cases; during the fourth week in 24 cases; during the fifth week in 8 cases; during the sixth week in 10 cases; and during the seventh week in 7 cases. In 40 cases the temperature became and continued subnormal throughout convalescence.

Two relapses occurred in 1 case with return of all the symptoms and one relapse occurred in 18 cases, with return of all the symptoms in 6. The interval of apyrexia before relapse averaged eight days; in 1 case the interval was twenty days, this was in a child aged ten years, whose primary attack had been most severe; there was a complete return of symptoms which lasted eleven days; in no cases except this one could the relapses in any way be attributed to change of diet. The average duration of the relapse was nine days, the temperature assuming the intermittent type.

With regard to the spleen, enlargement was made out by palpation in 20 cases; increased splenic dulness (no tenderness and spleen not felt) occurred in 3 cases.

There were typical rose spots in 67 cases and no rose spots in 13 cases. The rash appeared in the first week in 2 cases, in the second week in 42 cases, and in the third week in 23 cases. The spots came out in one crop in 28 cases and in several crops in 39 cases.

As to the bowels: (1) in 11 cases no diarrhœa occurred throughout the attack (constipation); (2) in 51 cases the stools were typical; (3) in 11 cases the stools were loose and offensive but not typical of anything; and (4) in 7 cases the stools were normal. Constipation was very troublesome in 36 cases, especially about the beginning of the third week. An enema of olive oil followed by an enema of glycerine proved by far the most efficacious treatment.

Hæmorrhage took place in 9 cases, 2 of which were fatal. In 1 case, that of a patient aged fifty years, the hæmorrhage was profuse (ten attacks in three days) and the total loss of blood was twenty-one and a half ounces. This patient made a very quick recovery. The temperature came down to normal after the last hæmorrhage and remained normal. Hæmorrhage occurred in 1 case during the second week, in 6 cases during the third week, in 1 case during the fourth week, and in 1 case during the fifth week.

With regard to nervous manifestations severe delirium occurred in 36 cases, troublesome insomnia in 5 cases, and melancholia in 3 cases. Typical epileptiform convulsions were present in 1 case; tremor and deafness were not frequent. As to complications, pneumonia occurred in 20 cases—right in 10, left in 4, and both in 6; pleurisy with effusion occurred in 1 case; suppurating glands occurred in 2 cases—axilla in 1 and neck in 1; albuminuria occurred in 13 cases—in 6 cases there was only a trace and in 7 cases there was from one-twelfth to one-sixth; retention of urine occurred in 3 cases; thrombosis of the long saphenous vein occurred in 1 case; hæmaturia occurred in 1 case; and abscess over the buttock occurred in 1 case. Mitral systolic murmur developed in 3 cases, lasting not longer than two weeks. Bradycardia, lasting two weeks, occurred in 1 case, the pulse falling to 40. The apex of the lung became impaired in 1 case. Purpuric eruptions appeared in 3 cases; 1 case was complicated by whooping-cough. No case of ulceration of the larynx occurred.

The death-rate was 16·25 per cent; 4 cases died during the second week, 5 during the third week, 3 during the fourth week, and 1 during the sixth week. Hyperpyrexia caused death in 2 cases, peritonitis (perforation) in 3 cases, pneumonia in 3 cases, hæmorrhage and exhaustion in 2 cases, cardiac failure (sudden) in 2 cases, and bronchitis and collapsed lung in 1 case.

The following points appear to me to be of interest: (1) the marked influence of severe hæmorrhage in the one case; (2) the infrequency in which the spleen could be felt; (3) the unusual period of twenty days occurring before a relapse; (4) the frequency of transitory albuminuria, the effect of the poison and not of nephritis; and (5) the presence of an epileptic attack during the course of enteric fever.

Newark-on-Trent.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

CASE OF HICCOUGH OF UNUSUAL DURATION AND SEVERITY; SUCCESSFUL TREATMENT BY GALVANISM.

BY GEORGE HERSCHELL, M.D. LOND.,

SENIOR PHYSICIAN TO THE HOSPITAL FOR DISEASES OF THE HEART, SOHO-SQUARE.

A WOMAN, aged twenty-four years, first attended my out-patient clinic on Oct. 26th, 1895, complaining of persistent hiccough, from which she had suffered for a week. The attack had been preceded by a prolonged period of overwork and worry. She was markedly anæmic but nothing else could be detected upon a physical examination. She improved very much under treatment consisting of iron, bromides, bismuth, and arsenic, but still continued to have a mild attack every few days. In March, 1896, she had a severe fright, after which the attacks greatly increased in severity and frequency. It was found that the medicines which formerly did her good were now without good effect and in the case of the iron it made her worse. She derived most benefit from bismuth with which I succeeded on two occasions in stopping the attacks for a few days. In each case as she was so anæmic (hæmoglobin 30 per cent., red corpuscles 2,300,000) I followed it up with iron, with

Digitized by Google

the result of immediately after two or three doses bringing back the hiccough as bad as ever. Valerian and assafœtida made her worse. In April, 1896, whilst waiting in the hall of the hospital she had the severest attack of hiccough I have ever seen in my life, and I thought at one time that she would die then and there from failure of the heart. I had her at once taken into the consulting room and a continuous current of about 8 milliampères applied to her, the anode being applied alternately for a minute or so at a time, stabile to the sides of the neck, whilst the kathode was placed upon the epigastrium. The effect was almost instantaneous, the attack passed away, and she had no return of it for several weeks. At the end of this time, however, the affection returned and she gradually became much worse, the attacks frequently lasting for a whole week with, as the patient declared, no intermission. There would then be an interval of a few days, during which time she would have merely several attacks in the twenty-four hours lasting an hour or so each, and then another long spell of almost continuous hiccough. As she daily grew weaker I decided to take her into the hospital in order to give a more extended trial to the galvanism which had been so successful on a previous occasion, and she was admitted on Nov. 27th, 1896. On admission it was recorded that the spasms were of such violence as to shake the whole body and give her the greatest distress. She slept very little as she was continually awakened by the hiccough which occurred, but with less frequency, during sleep. The treatment prescribed was the daily application of 15 milliampères of the continuous current, the anode on the epigastrium and the kathode on the small of the back; this was followed by the electric brush to the epigastrium. For the first few days she improved very much, but as this was not maintained the application was altered and the anode was applied alternately to the pneumogastric nerves in the neck whilst the kathode was placed on the nape of the neck. From this date she rapidly improved and was discharged on Jan. 21st, 1897, being directed to continue the treatment in the out-patient department and to attend twice a week for galvanism. This treatment was continued until May, 1897, when all attacks having ceased for over a month she was finally discharged. There has been no relapse.

The main point about this case is its extreme duration. Dr. Edward Liveing mentions a case in which hiccough occurred in paroxysms of twelve hours' duration twice a week for four years, but I have been unable to find another one reported of anything like the severity. It is a remarkable thing that the administration of iron should have invariably brought on an attack, and I think that the fact of its having done so goes far to suggest that in this case the affection had its origin in some irritation reflected from the stomach. This theory would also be strengthened by the fact that galvanism had little or no effect until it was applied to the pneumogastric nerves. Against the hypothesis that the affection was of an hysterical nature we have the facts that it occurred during sleep, that the medicines usually of service in hysteria were without effect, and that the suggestion involved in the daily manipulation with the galvanic current and electric brush did not cure until the former was applied in one particular manner.

Queen Anne-street, W.

A CASE OF POISONING BY CANNABIS INDICA.

By C. C. BAXTER-TYRIE, M.D. EDIN.

THE following case of poisoning by Indian hemp is not only interesting in itself but sheds a vivid light on the evils of the writing of so-called popular medical works by gentlemen of good professional standing and the dispensing by chemists of unauthorised prescriptions.

A few weeks ago I was called about 11 P.M. to see a young woman who had it was alleged "gone out of her mind." I thought at first I had to do with an ordinary hysterical fit, but closer observation convinced me that although the symptoms were a curious caricature of some hysterical attacks there were other symptoms that made such a diagnosis untenable. Fits of laughter and incoherent ravings alternated with comparatively lucid intervals. She complained of various hallucinations and delusions, chief of which were a complete perversion of the relations and elapse of time and a loss of identity. She was now herself, now again a different individual, and the modifications of her behaviour in relation to her dual personality were grotesque. I was entirely at a loss as regards the cause of the patient's condition until her mother volunteered that she had been taking Indian hemp. Like many other foolish people they had purchased a book on family medicine. The girl had suffered severely from headache for some time and after consulting the book they pitched upon Indian hemp as the likely remedy. A local chemist made them a dozen pills each containing one-half grain of the extract. The girl took one with no relief then two with a similar effect. She then concluded that they were "a fraud" and to demonstrate it swallowed the remaining nine with the result that I found her four hours after in the above-mentioned condition. I administered strong coffee and gave her a few doses of strychnine and she quite recovered on the following day. It is a well known fact that many victims of morphine and cocaine have derived their knowledge of these drugs from books on popular medicine, and it was very injudicious for the chemist to make up the pills without medical sanction.

Keighley, Yorkshire.

A CASE OF TETANUS TREATED WITH INJECTIONS OF SERUM.

By THOMAS G. C. EVANS, L.R.C.P. EDIN., M.R.C.S. ENG.

THE patient was a man, twenty-four years of age, who was admitted into the Budleigh Salterton Cottage Hospital on Oct. 7th suffering from severe injuries caused by the wheels of a loaded waggon passing over him. He had a badly comminuted fracture of the left leg immediately below the knee with a great deal of bruising of the soft parts around but the knee-joint was uninjured and the larger vessels were intact; he had also a large ragged wound over the right knee. The left leg was put upon a back splint and slung and the wound of the right knee was carefully cleansed and dressed. During the next few days the skin about the seat of injury gave way in several places and the leg was put upon a perforated metal splint in order that it might be irrigated with as little movement of the limb as possible. On Oct. 23rd he complained of a feeling of slight stiffness of his neck which he thought was due to taking his food in a recumbent position; his temperature which had been almost normal for the last few days rose to 101° F. and he was drowsy. At this time the wound of the right knee was almost healed. On the left leg there were several large granulating surfaces where the skin had given way and two or three sinuses leading into the fracture. He took his food well but nothing solid after 12 30 P.M. and he had a good night. On the 24th the stiffness of the neck and jaws was increased. The patient's temperature was 98·4° in the morning and 100° in the evening. He was cheerful and took large quantities of liquid food well. After a consultation with my colleagues Dr. Walker and Mr. Semple it was decided to amputate the left thigh. This was done at 11 P.M. On recovering from the anæsthetic after the operation the patient had a severe spasm. He passed a fairly good night. On the 25th his jaws were rather less stiff, he passed a fairly comfortable day and took his food well. The morning temperature was 100 8° and the evening temperature 103°. The stump was dressed at 8.30 P.M. and 10 c.c. of antitetanic serum were injected. He was very restless the first part of the night but slept better towards morning. On the 26th there was more stiffness of the jaws and neck and he could not move his head from side to side His temperature was 99° in the morning and 101° in the evening. At 10 A.M. 10 c.c. of the serum were injected. An ounce of castor oil was given. He had not quite so good a day, being restless. At 5.30 P.M. an enema with olive oil was given and was followed by free action of the bowels. At 8.30 P.M. the stump was dressed and 10 c.c. of the serum were injected. He felt better that evening and passed a better night, having good sleep after 4 A.M. On the 27th the stiffness was much the same. At 10 A.M. 10 c.c. of the serum were injected. He had a much more comfortable day and took nourishment well. At 5 30 P.M. an enema was given but there was no action of the bowels. At 8 30 P.M. the stump was dressed and 10 c.c. of the serum were injected. He passed a restless night. His temperature was 101° in the morning and 102° in the evening. On the 28th the stiffness of the jaws was

Digitized by Google

much the same; there was a good deal of general muscular twitching during the day. At 10 A.M. 10 c.c. of the serum were injected. He had a comfortable day. An ounce of castor oil was swallowed with difficulty. At 5.30 P.M. an enema was given and was followed by slight action of the bowels. At 8 30 P.M. the stump was dressed and 10 c.c. of the serum were injected. His temperature was 101° in the morning and 102·4° in the evening. He passed a quiet night but had not much sleep and wandered a little. He had more difficulty in taking food and was fed by a tube. On the 29th he said he felt better. At 10 A.M. 10 c.c. of the serum were injected. At 2.15 P.M. he had a spasm on waking from a short sleep and lost a little blood from his mouth, probably from biting the tongue; this frightened him a good deal. At 5 30 P.M. a castor oil enema was given, followed by a better action of the bowels. At 7 P.M. the stump was dressed and 10 c.c. of the serum were injected. The temperature in the morning was 102° and in the evening 103·4°. The patient passed a quiet night; he had not a great deal of sleep and was slightly delirious. On the 30th he was very bright and in good spirits, saying he felt better. At 9.35 A.M. he had a sudden spasm with a slight flow of blood from the nose and the mouth. He died at 9 40 A.M. The temperature in the morning was 101 4°.

This was a disappointing case, the length of time between the accident and the first symptoms of tetanus, its chronic character and the almost entire absence of convulsive spasm all gave reason to hope that the result would be favourable. Feeding presented no difficulty, liquid food being always taken in large quantities; an average amount in twenty-four hours would be six eggs, from five to six pints of milk, one pint of beef-tea, and from ten to twelve ounces of whisky. Restlessness was overcome and sleep obtained by opium given in the form of nepenthe, usually one dose of twenty minims during the day and one of thirty minims given after the dressing in the evening, followed by another of thirty minims four hours later. The serum injections had no effect whatever as far as could be seen, either good or bad, and the patient suffered no inconvenience from them.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procemium.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

TWO CASES OF HYDRONEPHROSIS.

(Under the care of Mr. EDMUND OWEN.)

THE following cases are very good examples of the two commonest causes of hydronephrosis in children. In the first the condition was apparently congenital in origin, though we cannot say what malformation gives rise to hydronephrosis in such cases; in some instances congenital narrowing of the ureter at its renal insertion has been found [1] A case very similar to Mr. Owen's was recorded in THE LANCET by Mr. Arbuthnot Lane.[2] The second case occurred in a private patient under the care of Mr. Owen but we have thought it well to include it in the "Mirror of Hospital Practice" as it is in several respects similar to the first case and yet the two have many points of contrast, so that they may be usefully studied together. In this case traumatism was the cause of the hydronephrosis and the result of leaving the ruptured kidney has been eminently satisfactory. The only other frequent cause giving rise to hydronephrosis in children is the impaction of a stone in the ureter.

CASE 1. *Hydronephrosis; operation; recovery.*—A girl, aged thirteen years, was sent to the hospital by Dr. Houston Davson for a tumour of the left side of the abdomen which had been noticed only two weeks. The child had been steadily losing flesh, however, for a year, and had recently been complaining of abdominal pains; she also had had attacks of vomiting for a long while. There had been no history of colic or of hæmaturia, and there was no suggestion of tuberculosis. A large globular swelling extended from the left side of the abdomen across the median line; there was resonance around it except to the left and behind; there was no bulging in the loin. On the day after her admission, without any exploratory aspiration, Mr. Owen opened the abdomen in the median line, and, exposing the tumour, sought for possible obstruction of the ureter, and finding none emptied the hydronephrotic sac, tied the pedicle, and removed the cyst. The right kidney was larger than normal, but it appeared healthy. The tumour removed consisted of one large cyst about the size of a fœtal head, occupying the position of the pelvis of the kidney; the kidney-tissue was stretched, and involving the upper infundibula was another dilatation which opened freely into the larger cavity. A considerable amount of healthy renal tissue remained at the lower part and presented congenital lobulation.

Apparently the case was one of congenital cystic dilatation of the kidney; at any rate, no obvious cause of the hydronephrosis could be discovered. The girl made a complete recovery. Her attacks of vomiting ceased and she grew strong and plump.

CASE 2. *Traumatic hydronephrosis; nephrotomy; recovery.*—The father of this child, who was a medical man, gave the following account:—On the morning of April 26th, 1897, the patient, a boy aged seven years, was kicked on the front of the left side of the abdomen by a horse. He immediately became blanched, but complained of no great pain; he was carried home. On examination over the seat of the injury no abrasion or discolouration was found. The muscles of the abdomen on the same side were tender and tense, but beyond this nothing abnormal was detected. Persistent vomiting supervened, lasting twenty-four hours. On the evening of the accident a considerable quantity of blood was passed with the urine, and this continued until the 28th, when the urine was apparently free from blood. No severe pain was complained of, but there was tenderness over the seat of the injury. He was kept quiet, and took nourishment well after the vomiting ceased; the temperature remained below 100° F. On May 1st he was removed to London to be under the care of Mr. Rayley Owen, a tedious journey of two hours, without ill effect, and he improved so much that on the 5th he was anxious to get about, and was permitted to do so. There was nothing abnormal to be discovered on examination over the seat of injury. He remained fairly well until May 11th, when he complained of left lumbar pains and had some return of vomiting. There was no rise of temperature. On the 13th a tumour the size of a large orange was made out in the left lumbar region circumscribed and not tender. This increased rapidly without constitutional disturbance beyond occasional vomiting and sharp paroxysmal pains, which were referred to the lumbar region and the front of the left thigh. These pains increased in severity as the tumour grew larger. On May 22nd the tumour was aspirated by the loin and a wine-bottleful of bloody urine was withdrawn. The tumour at the time of the aspiration extended above to the false ribs and below to the crest of the ilium. After the aspiration the vomiting and pain ceased and the tumour disappeared, but on the third day the tumour began to refill, and with this the vomiting and pains reappeared. A second aspiration was therefore performed and with a like result. At this time Mr. Bennett kindly saw the boy with Mr. Owen, and as the tumour had recurred it was advised that an incision should be made in the loin for exploration and for needful drainage. This being done the kidney was found to be torn right across. The upper part comprised about four-fifths of the gland and the lower fifth was separated from it by a considerable space in which blood-stained urine was collected. The capsule of the kidney had been completely torn across by the kick, and the blood and urine had evidently collected in the loose tissue around the kidney and between the fragments. A drainage-tube was placed in the wound for a few days and the boy made a complete and uneventful recovery. The father wrote under date Nov. 10th: "The boy is very well and seems quite strong."

Remarks by Mr. OWEN.—The features common to these two cases are fulness in the renal region and persistent

Digitized by Google

vomiting. Taken together these symptoms are more than suggestive. As there was some doubt as to the nature of the tumour in the first case it was approached by abdominal section. It could, of course, have been removed with equal ease by the loin without opening the peritoneum; but when there is room for doubt as to the nature of a tumour in the renal region the operator does well to make himself master of the situation by opening the abdomen through the median or semilunar line.

The second case is instructive in that it shows that though a child's kidney is broken right across it does not necessarily demand removal. Probably the actual rent was so far below its equator that the urine secreted by the chief part of it was eventually enabled to find its way along the ureter. And I think that it would be well in all cases of nephrotomy for ruptured kidney in children to give the gland and its duct the off-chance of rearranging matters to the physiological advantage of the individual. If persistent lumbar fistula gave evidence that the injury was such as to be wholly beyond the reparative power of nature, nephrectomy could be resorted to.

VICTORIA INFIRMARY, GLASGOW.

A CASE OF EXTENSIVE CARCINOMA OF THE STOMACH FOR WHICH JEJUNOSTOMY, AS MODIFIED BY MAYDL, WAS SUCCESSFULLY PERFORMED.

(Under the care of Mr. A. ERNEST MAYLARD.)

FOR the notes of the case we are indebted to Dr. Weir, resident house surgeon.

A man, aged fifty years, was admitted to the Victoria Infirmary, Glasgow, on May 7th, 1897. At the beginning of March of this year the patient began to feel himself becoming gradually weaker and rapidly losing flesh. Except these symptoms he noticed nothing until a month previously, when he began to vomit his food. The ejection was frequently preceded by an attack of severe coughing. Often in the morning and just after rising and before his breakfast he would vomit a few mouthfuls of clear, watery fluid quite bland in character. No blood appears at any time to have been seen in the vomit or in the stools, which he stated were perfectly natural. Until recently he had felt no marked pain in his stomach, but he had entirely lost his appetite. On admission to the hospital he was seen to be a sallow-complexioned man; he was much emaciated and much enfeebled. He complained of pain in the region of his scapulæ, but he stated that his worst pain was felt when he took food. So much suffering did this cause that he preferred to desist from any attempt. On examination of the abdomen a swelling was seen on the left side of the epigastrium which was hard to palpation, quite painless, rounded in shape, and moved slightly with respiration. The dulness on percussion was continuous with that over the liver. It was found that by a careful regulation of the diet it was possible for him to take food without it being vomited, nevertheless its ingestion was always accompanied with pain. A test breakfast was administered, and the gastric contents when removed were examined by Günzberg's method for hydrochloric acid, but no reaction was obtained. Endeavours were made to wash out the stomach, but the tube caused so much irritation that the attempt had to be abandoned. Nutrient enemata were administered every four hours and one was given just prior to the operation.

The operation was performed on May 18th with the assistance of Dr. Grant Andrew and Dr. Weir. A median incision was made above the umbilicus, and after opening the general peritoneal cavity a digital examination of the stomach was made. It was then found that the organ was extensively implicated, the greater part of the body consisting of a hard nodular mass of tumour tissue. An attempt was first made to bring up the duodenum with the object of performing duodenostomy, but this not being possible Maydl's method of performing jejunostomy was proceeded with. The operation lasted one hour and ten minutes and was not followed by vomiting. The patient rallied well. On the second day peptonised milk was given by the abdominal wound, and this was repeated every three hours. The administration of nutrient enemata was also continued. A marked diminution of the tumour was observed on the fourth day. On the fifth day a good motion passed; for the first time also there was regurgitation of bile from the abdominal orifice. A little fluid nourishment was given by the mouth, and this appeared to cause no pain. On May 28th, that is, ten days after the operation, the patient confessed to feeling much better; his cough, however, was proving more troublesome, and whatever improvement had taken place in his gastric condition seemed more than counterbalanced by the trouble he was beginning to suffer in respiration. At times his cough was very troublesome. Considerable regurgitations of bile occasionally took place, and at times also the injected food was returned. On the eighteenth day after the operation the Murphy's button used at the operation to implant the proximal end of the divided jejunum into the distal segment was passed in the motions without causing the patient any discomfort. After this the patient's lung trouble continued to increase, his cough becoming persistent, until on June 8th he died just three weeks after the operation.

Necropsy.—At the post-mortem examination, which was made by the pathologist, Dr. Galt, the lungs were found to be extensively involved, the left being consolidated and in places gangrenous. On examining the stomach tumour tissue was found involving chiefly the lesser curvature, but extending from this on each side down to the greater curvature. Microscopical sections of the growth showed it to be colloid carcinoma; spaces were seen almost entirely filled with colloid material to the exclusion of cellular elements, although here and there existed well-marked groups of carcinoma cells. An examination of the parts operated upon showed perfect union between the two attached portions of the intestine. A well-marked canal existed between the united segments with no signs of any contraction.

Remarks by Mr. MAYLARD.—The operation of jejunostomy, as usually understood, resembles in its performance those other operations upon the alimentary canal which possess in their terminology a similar suffix; that is to say, it consists in fixing the viscus to the abdominal parietes and maintaining for a period, either temporary or permanent, a fistulous connexion with the outside of the body. Many different methods are employed in performing the operation, and the various modifications introduced have for their chief object the prevention of any escape of the contents of the bowel. Maydl, however, has so modified the operation that it almost belongs to a class of its own so much does it differ from those usually understood by the term jejunostomy. The operation known as Maydl's consists in first opening the abdomen in the middle line above the umbilicus and then seeking for the upper end of the jejunum; when this is secured it is brought out of the abdominal wound and divided. Another opening is made in the side of the distal segment into which the proximal is implanted. This union is effected either by stitching or, as performed in the above case, by a Murphy's button. The orifice of the distal segment is lastly stitched to the parietal wound (see diagram). A precisely similar operation has been

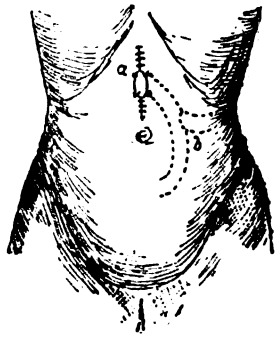

Diagram of Maydl's operation for jejunostomy. *a*, orifice of jejunum stitched to parietal wound; *b*, lateral implantation of upper segment into the side of the lower.

devised in place of gastro-enterostomy, the only difference being that the distal free end of the divided jejunum is planted into the stomach instead of into the abdominal parietes. The operation of jejunostomy, by whatever method performed, is only called for in extreme cases of gastric carcinoma, and it is therefore essentially an operation of expediency rather than one of necessity, one which aims at the relief of suffering for the comparatively short time that life is likely to last. From the point of view of relief given the present case seems one worthy of record, for the great suffering which the patient endured whenever nourishment was administered was entirely removed by the

Digitized by Google

giving of all food through the jejunal orifice. The stomach thus obtained complete rest, while the operation itself produced but slight temporary disturbance to the patient. However, although the patient constantly expressed himself as greatly relieved by the operation I confess I was somewhat disappointed at the regurgitation of bile which took place from time to time through the artificial orifice. This, I believe, was due to planting the proximal end of the jejunum into the distal segment at a point too near the orifice. In a second attempt to perform the same operation I shall endeavour to make the union some few inches further down. This will of necessity entail a more extended severance of the mesentery so as to admit of the required separation of the two cut extremities, for without such division it would be impossible to bring up the distal extremity to the surface of the abdominal parietes without drawing up also the proximal end. There was a point of considerable interest observed in connexion with the feeding of the patient. It was found that although food properly prepared and peptonised was freely given through the artificial orifice and retained the man seemed to be gradually getting weaker, more than could be accounted for from any other cause except that of insufficient nourishment. I thought it just possible that absorption and assimilation were not taking place owing to the want of bile and possibly pancreatic juice, and that these failed in being secreted owing to the absence of any normal stimulant conveyed through the usual channels of gastric ingestion. We therefore commenced giving a little bland liquid food by the mouth, and with the best results, for the patient soon showed signs of regaining strength. It was further noted that food so taken into the stomach no longer caused the acute pain it previously had. The temporary rest which had been given to the viscus by the operation had apparently been the means of allaying a good deal of its irritability.

Medical Societies.

CLINICAL SOCIETY OF LONDON.

Calot's Operation for the Immediate Reduction of Angular Deformity of the Spine.

A MEETING of this society was held on Nov. 26th, Mr. LANGTON, President, being in the chair.

The PRESIDENT read an English translation of the paper read by M. Calot at the last meeting, which was published in THE LANCET report of Nov. 20th. — Mr. MAKINS (honorary secretary) read some remarks which had been contributed by M. P. Rédard, of Paris, who was unable to be present. M. Rédard considered that the method was a very valuable one in certain cases and was convinced from his own experience in some forty cases that if reasonable precautions were taken it was effectual and free from risks. He pointed out, however, that all cases of Pott's curvature were not amenable to immediate reduction and he only advocated its use in those cases in which the reduction was easy and he deprecated its employment for the reduction of irreducible ankylosed curvatures. He held that neither size nor duration of the curvature was a contra-indication for the method but that all cases were suitable which were reducible with moderate force, and he was strongly opposed to rough or violent manipulations. M. Rédard sent photographs of the apparatus which he employed for the purpose of effecting reduction and which enabled him almost to dispense with assistance and avoided the necessity for the prolonged compression of the boss during the setting of the plaster. The exact amount of traction employed was indicated by a dynamometer. When applying the plaster jacket too thick a layer of cotton wool should not be placed next to the skin as it hindered the secure maintenance of the spine in position. He had met with no unpleasant results in any of his forty cases, but had observed indisputable correction of the deformity in many severe cases.

The discussion on the paper by Mr. Robert Jones and Mr. Tubby, adjourned from the last meeting, was then continued by Mr. WATSON CHEYNE, who said that he considered that the subject was hardly ripe for discussion as so short a time had elapsed since the operations were performed. Undoubtedly the results were satisfactory from an orthopædic point of view, but it must be remembered that in these cases the surgeon was dealing not only with a deformity but with disease. As regards the ultimate effect of the treatment on the diseased bone at this early period they could only fall back on general experience of the behaviour of tuberculous disease in bone. He admitted that the absence of serious accidents had surprised him, but a cure could not be said to have taken place unless and until firm bony ankylosis had occurred. Unpleasant consequences appeared to be less frequent than after similar interference with ankylosed tuberculous joints such as the knee. Spinal abscess was, however, very slow in developing and he would not consider that any of the patients operated on within the last few months were free from danger from this sequela. In order that the disease might be actually cured two things were necessary. First, the tuberculous tissue must have disappeared or become encapsuled and the conditions did not look favourable for this issue. One or several cavities would be produced filled with blood-clot, fragments of cancellous bony tissue, and cheesy material, conditions which would favour extension of the disease or formation of abscess. Secondly, ossification and consolidation must take place. As a rule, in contrast to what happened in acute necrosis, there was remarkably little new bone formed in tuberculous disease of bone. If an ankylosed tuberculous joint were examined it would be found that there was a very small surface united by bone most of the union being fibrous. He doubted whether bony union would occur anteriorly. Calot held that union would take place posteriorly, but although some museum specimens showed that this had occurred little trace of it could be found in recent cases. Some of the cases recorded by Calot and others had been reduced after the curvature had existed for periods of from six to eleven years, showing that even in this time firm ankylosis had not occurred under circumstances not less favourable than those after forcible reduction. He thought if the operation were performed at all it would be well to follow Calot's plan of freshening the adjacent edges of the laminæ of the vertebræ and uniting the periosteum at the same time. He did not believe that the results obtained by this method would be better than by double extension with weights followed by prolonged recumbency, improvement following even with a constant weight of eight pounds. He always adopted this plan before performing laminectomy which he believed was necessary in only a few cases. The method was absolutely on its trial and he considered that a sufficient number of operations had been done to test its value although several years must yet elapse before the ultimate effect on the cases which had been brought before the society could be estimated, and he thought that before any more cases were treated its effects on these early cases should be known.

Mr. BARWELL said that the mortality had been surprisingly small. He thought that some attempt would have been made to give some account of the effects on the bones as found at the necropsies on these fatal cases. The specimen shown by Mr. Murray at the last meeting did not satisfy him as he wanted to know the condition of the whole spine *in situ*. He considered that the method was in an experimental stage and that accurate judgment could not be passed on it for some years.

Mr. NOBLE SMITH said that he had seen several cases in which immediate reduction of bone was accidentally brought about and the results in those cases were such as to make him sceptical about the advisability of Calot's operation. The first case was that of a child who suffered from active caries the result of a fall and leading to the formation of a curvature. After eighteen months' rest he was able to get about, but he fell again and the ankylosis not being firm the curvature was straightened. The caries again became active and abscesses formed, the child dying three years later. The second case was that of a youth, aged sixteen years, who had a large rounded curvature. When the spine was forcibly extended the curvature was straightened out, but general tuberculosis ensued, and the patient died. The third case was that of a boy, aged seven years, who had extensive disease of vertebræ. He had adopted the posture of lying prone on his elbows and knees, which had the effect of straightening out the curvature. He died from tuberculous meningitis two years later and on examining the spine it was found to be united by bone anteriorly but this new bone was of such loose and friable quality that it entirely crumbled away when the bone was macerated. He

Digitized by Google

thought that the suggestion of Mr. Jackson Clarke that new bone might be thrown out from the anterior common ligament and help to fill the cavity was a very likely one. He showed an elderly woman suffering from caries in whom the deformity was practically reduced by wearing a suitable apparatus which had enabled her to resume her occupation.

Mr. JACKSON CLARKE said that of the two factors, the disease and the deformity, the former was of primary importance. The deformity tended to increase after the disease was checked owing to the adaptive growth of the healthy portions of the spine, which were "kinked down" at the diseased vertebra. For some time past he had used Chance's splint as an efficient means of arresting the disease. He had tried the method of immediate reduction in the case of a girl with a sharp angular curvature which had only existed for two months. The deformity was reduced without much force being used, a distinct crack of the bone being heard. A plaster cuirass strengthened by metal strips was then applied while the manual extension was kept up. The plaster jacket had to be removed after a few weeks and the curvature was found to have returned. Reduction by forcible extension was again performed and this time the spine was put up in an over-extended position. Five weeks later there was considerable diminution of the curvature and on extending the spine there was some slight cracking but no further yielding. The child was now going to have a Chance's splint with an occipital band to control the movements of the head. He thought that the splint shown by Mr. Jones confined the whole body too absolutely. He recalled one case in which there had been absolute fixation in such a splint for four years, but this did not prevent the formation of a boss, and the child's general health suffered. He thought that two years' fixation in such a splint would be a very serious thing for the child especially if any bronchitis occurred. He thought that the best plan was to employ fixation for three months and then apply a Chance's splint.

Mr. W. G. SPENCER said that the operation would allow the subsequent treatment to be commenced with the spine straight. It did not appear to offer any danger to life, and there was no evidence that any of the cases had been made worse. He thought that ossification would go on as well after this operation as before. Bone would probably be thrown out by the anterior common ligament. He did not think that the post-mortem specimen shown by Mr. Murray taught much. The gap which was shown might have been formed post mortem as it was empty, not even containing blood as would have been the case if it had been formed during life. He believed that these cases would be found to have ankylosed as firmly as cases treated by other methods.

Mr. COTTERELL said that he had operated on two cases. The first was that of a child who had been treated for dorsal caries and paraplegia for five months by rest without improvement. The curvature was relieved by forced extension in October and the paraplegia was rapidly passing off. In the second case an angular curvature was easily reduced, but while putting the jacket on the child stopped breathing and artificial respiration had to be resorted to. Undoubtedly the position required for the extension made things very difficult for the anæsthetist.

Mr. THELWALL THOMAS (Liverpool) considered the objections to forcible straightening of the spinal column to be based on a wrong reading of museum specimens, whose very existence depended—too often, alas!—upon inefficient treatment. The ordinary treatment of spinal caries never really prevented undue pressure of the softened bodies on each other, and it was easy to account for the large mortality which they all knew existed from abscesses and dissemination of tubercle, brought about by this constant grinding pressure. The theoretical objections that were raised to the new treatment—namely, (1) that paraplegia would result, (2) that abscesses would occur, and (3) that dissemination of tubercle would be brought about—had all been disproved so far and the only pathological item which remained now to be settled in the minds of some was what filled the "gap" assumed to be always produced by forcible straightening. The practice of surgery consisted almost entirely of making "gaps" which nature obligingly filled up (even after such proceedings as scraping tuberculous bone) and certainly they ought not to worry about that.

Mr. A. E. BARKER endorsed all that Mr. Watson Cheyne had said and agreed that it would be well to wait to see the result in the cases already operated on. He mentioned a case in which a fatal acute pleurisy followed the rupture of a spinal abscess when a patient was suspended in a tripod for the application of a plaster jacket and he thought that a similar accident must be expected in a certain proportion of the cases. He thought that the evidence was quite against the possibility of the new formation of bone in sufficient quantity to fill up the gap. M. Calot stood by the analogy between the ankylosed spine and an ankylosed knee and agreed that what would be bad for one would be bad for the other. Mr. Barker would anticipate extension of the disease if he attempted forcibly to extend a tuberculous knee, and he thought that that was the general experience of surgeons.

Mr. ROBERT JONES expressed his satisfaction that the subject had been so well discussed, even though some speakers had been pessimistic. He reminded the society that the object of the paper was to lay certain clinical facts before them in relation to the immediate straightening of spines which were at complete variance with traditional and present belief. In no case had abscess, dissemination of tubercle, or paraplegia followed reduction. Instead of producing paraplegia it had in several instances by relieving pressure on the cord cured it. Mr. Watson Cheyne had urged that when the backs were straightened they were not cured. The same argument might be applied to neglected deformities following tubercle in joints. Mr. Watson Cheyne and Mr. Barker deprecated the immediate reduction of tuberculous hips and knees. Mr. Jones constantly practised such reductions without any of the evils referred to following. The fatal character of Pott's disease was admitted and the difficulties of governing the deformity by mechanical means were so well known that some radical effort should be made to bring about a better state of things. When he first practised this method with a full sense of the responsibilities friends warned him of paraplegia, abscess, and dissemination. Now these dangers had proved groundless they were told to beware of the "gap." Had he feared the separation of bodies he had no right to operate upon a single case, but speakers who advocated the removal of intra-articular pressure in joints deprecated it in the spine which exhibited the *strongest* tendency to bony exudation. Fixation could be more efficiently applied to a straight than to a *crooked* spine, and prevention of the crunching of vertebræ from superincumbent weight should tend to firm and rapid union. He had just received a communication from M. Calot stating that he had patients walking without supports after the practice of immediate reductions, and in no instance did the spine "wobble." Such a fact should altogether dissipate the pathological fear. Mr. Tubby and he very cordially accepted the suggestion of the President to show cases when sufficient time had elapsed.

Mr. TUBBY said with reference to Mr. Murray's communication that gentleman had granted all the points of their argument but had then branched off into *speculations* and had spoken of the possibility of a "wobbly hump" resulting, as if such an event were likely, in the spine. He thanked Mr. Watson Cheyne for his criticism but wished to join issue with him on this point—viz., that the cure of the deformity and of the disease were entirely different. In dealing with tuberculous joints such as the hip and knee one object in treatment was to separate the parts and give them rest, and this was precisely what was done in the spine when it was straightened. Mr. Tubby added that he thought the reason why a diseased spine took so long in healing was on account of the want of complete rest. As to the disputed question of ossification taking place in the gap formed by reduction, certain specimens, notably one in the St. Thomas's Hospital museum and another bearing on the question in the Hunterian Museum were alluded to. In the first-named specimen ossification in, and filling up of, the gap had evidently occurred during the ordinary course of the disease the back having been kept straight. As to the plea uttered by Mr. Watson Cheyne and Mr. Barker that Mr. Jones and he would now withhold their hands, there was no reason for doing so. Abroad this treatment was still being extensively tried, 600 cases, according to M. Calot, having been operated upon in France and so long as no danger or undue risk was incurred he failed to see the necessity for reaping experience at second-hand.

HARVEIAN SOCIETY OF LONDON.

Hernia of the Abdominal Cicatrix and Operations for its Cure.—Empyema of the Antrum of Highmore.

A MEETING of this society was held on Nov. 18th, Mr. MILSON, the President, being in the chair.

Mr. ALBAN DORAN read a paper entitled Hern

Digitized by Google

of the Abdominal Cicatrix and Operations for its Cure. This paper was given at length in THE LANCET of Nov. 27th. — Mr. BUTLER-SMYTHE congratulated his colleague on the success attending his efforts to relieve those women suffering from ventral hernia. Mr. Doran had his sympathy in that one instance where the hernia had returned after operation, but perhaps it might be some consolation to him to know that there was no surgeon living of whom it could be said that he had not had many such cases following his operations. He (Mr. Butler-Smythe) ridiculed the idea of operators stating "that they could not trace a single case of ventral hernia in their own practice." The fact was that when an operation for the removal of an abdominal tumour was unfortunately followed by a hernial protrusion, varying from the size of a walnut to that of a pouch reaching from the ensiform cartilage to the pubes and containing the greater portion of the abdominal contents, it was, to say the least, improbable that those patients would return to the original operator but rather would seek fresh advice. Ventral hernia would now and again occur no matter how careful the surgeon might be in the matter of closing the abdominal wound. In most of the cases read that evening it seemed that the hernia had occurred at either end of the abdominal scar, and this looked as if the closing of the upper and lower angles of the wound had been imperfectly sutured. In his opinion the chief point in sewing up the wound was to approximate the sheaths of the recti muscles as accurately as possible. Union of fibrous tissue was stronger and more permanent than that of muscle or skin. He was convinced that if attention were directed to the accurate suturing of the aponeurosis the chances of hernia would be greatly diminished.—In reply to Mr. Butler-Smythe Mr. DORAN remarked that the edge of the rectus muscle as well as its sheath should always be included in the suture whether the aponeurotic layer were united separately and continuously or simply closed by deep interrupted sutures passed through all the layers of the parietes.

Mr. E. W. ROUGHTON read a paper on Empyema of the Antrum of Highmore. He limited his remarks to those cases in which the ostium maxillare was patent and the symptom complained of was a discharge from the nose. The discharge was usually purulent, unilateral, intermittent, and affected by posture. An examination of the nose by speculum and light revealed pus in the middle meatus; after cleansing the nose pus reappeared when the head was hung down and towards the unaffected side. As aids to diagnosis he mentioned transillumination of the antrum, catheterisation through the ostium maxillare, percussion of the teeth, and exploratory puncture through the nose, alveolus, or canine fossa. He also insisted upon a careful examination of the teeth in the upper jaw. A carious first or second molar was a very common cause of empyema, but any tooth in the upper jaw might involve the antrum; it was also important to bear in mind that a tooth which was quite free from caries and to the ordinary observer apparently healthy might have an alveolar abscess at its root. The indications for treatment were—(*a*) removal of the cause by dealing with dental or nasal disease; (*b*) evacuation and drainage of pus; (*c*) antiseptic irrigation; and (*d*) removal of morbid tissue (when present) from the antrum. He advocated that an alveolar tube should be fitted in every case. In acute or subacute cases a cure would often be effected provided that the tube was of large calibre (at least an eighth of an inch) and that its upper extremity was on a level with the floor of the antrum. The length of the canal from the gum to the floor of the antrum could be best determined by means of a small *catheter à boule* used in the same way that it is used to measure the position and length of a stricture of the urethra. In chronic cases or those that resisted treatment by the alveolar tube for six months it was necessary to open the antrum through the canine fossa and thoroughly remove all morbid tissue found therein. The canine fossa operation should always be supplemented by an alveolar tube to facilitate drainage in the after treatment. He had had no experience of opening the antrum through the inferior meatus of the nose as he considered that there was no case which could not be effectually treated by the alveolar tube with or without the canine fossa operation. In some cases the nasal discharge continued after draining the antrum; attention should then be directed to the frontal sinus or fronto-ethmoidal cells.—Mr. LENNOX BROWNE remarked on the great improvement observed in the general health of patients who had been efficiently treated for empyema of the antrum.—Dr. SCANES SPICER had yet to see a complete cure of a case of chronic antral empyema by the ordinary irrigation tubes inserted through the alveolus. By that he meant—(1) permanent cessation of pus flow, bad smell in the nose, and pain; and (2) permanent removal of tube, no irrigation worries, and healing of fistula in a case of antral empyema of several months' or years' standing and in which the antrum was not merely a receptacle of fronto-ethmoidal pus. Anything short of this he could only regard as a very equivocal palliation, for, indeed, in many cases the irrigation apparatus aggravated discomfort by causing recurring acute sinusitis with pain and, further, the taste of pus was always in the mouth. He had known many cases that had endured this for years. After giving the alveolar tube methods a trial for years with the coöperation of the most skilful dentists he had been compelled to drop these methods as never successful in chronic cases such as chiefly came under his notice. At one time he had a large accumulation of these failures, many of which he subsequently submitted to the radical operation, and if the antral empyema were uncomplicated these had been completely cured, usually in a very few weeks. During the last eight years he had operated radically on well over thirty cases.[1] The points he regarded as essential for the success of the radical operation were (1) a large opening through the canine fossa; (2) thorough curettement of diseased antral mucosa; (3) very free counter opening from the nose into the antrum; and (4) no drainage apparatus (the air blast suffices to clear the antrum of pus until the mucosa is healthy). No bad results, certainly no disfigurement or sinking of the cheek, had occurred in any of his cases.—Dr. WILLIAM HILL had experience of cases in which an alveolus had been drilled and a tube inserted without marked relief, so that it was necessary to make an opening in the canine fossa and scrape out the antrum.—Mr. SEFTON SEWILL said that the operation of puncturing through the alveolus was a simple one and one which in conjunction with a permanent drainage apparatus was considered efficient treatment by distinguished surgeons.—Dr. DUNDAS GRANT spoke of the frequency with which the uncinate process of the ethmoid became diseased and led to accumulation of pus in the antrum. Such cases were purely nasal and demanded nasal treatment.

LIVERPOOL MEDICAL INSTITUTION.

Removal of Epithelioma from the Larynx by Thyrotomy.—An Account of Nine Operations on the Liver.—Ice-cream as a Vehicle of Infection in Typhoid Fever.—Details of the Clamp and Cautery Operation for Hæmorrhoids.

A MEETING of this society was held on Nov. 18th, Dr. RICHARD CATON, President, being in the chair.

Mr. BARK showed a case of Removal of Epithelioma from the Larynx by Thyrotomy. The patient was a man, aged forty-one years, from whom he had removed the right vocal cord, ventricular band, and arytenoid cartilage for epithelioma by thyrotomy. Hahn's tube was used for seven days. The patient made an uneventful recovery. The man had suffered from hoarseness for two years previously to the operation. There was now, eight months after the operation, no sign of recurrence. He had a strong though hoarse voice.—Dr. HUN drew attention to the duration of the disease and said that it was not unusual for a malignant papilloma to remain quiescent for some years causing no symptoms except hoarseness. He preferred to remove Hahn's cannula immediately after the operation on account of the risk of septic pneumonia.—Mr. RUSHTON PARKER mentioned a case of thyrotomy where he had removed Hahn's tube immediately but had been obliged to re-introduce it later.

Mr. RUSHTON PARKER read notes of Nine Operations on the Liver. Three were for abscesses, four for hydatids and two were cases of gall-stones impacted in the ducts. All were successful. In one case of hydatid, punctured less than twenty-four hours before extraction of the cyst, universal peritonitis had resulted. There were vascular injection of the peritoneum and purulent effusion with large non-adherent flakes in the pelvis. This was treated by copious washing and by pelvic drainage through an additional suprapubic

[1] See Proceedings of the Laryngological Society of London, Proceedings of the West London Medico-Chirurgical Society, and Brit. Med. Jour.

Digitized by Google

incision. The desirability of avoiding puncture of hydatid cysts except when the operator is prepared to remove the cyst immediately and certain features in the diagnosis of hepatic abscess were dwelt upon.—Dr. BRADSHAW wished to emphasise the fact that the absence of pyrexia for longer or shorter periods by no means excluded hepatic abscess. In the third case of Mr. Parker's series the temperature was normal or sub-normal during the five days that the patient was in hospital before the operation. The abscess when opened was found to contain three pints of pus. The diagnosis was based upon a history of tropical diarrhœa, pain in the right shoulder, tenderness in the region of the liver, and remarkable enlargement of the organ in an upward direction.—Mr. PAUL said he used the aspirator for hydatid of the liver in children and had met with several cures. In both abscess and hydatid he had had the misfortune to meet with cases in which a communication had been established with the bile-ducts previously to operation. They all ended fatally sooner or later. In reference to gall-stones he thought the question of recurrence extremely important. Apart from inaccessible stones left behind it seemed to be very rare.—Dr. E T. DAVIES thought the use of the exploring needle for diagnostic purposes was to be deprecated unless immediately followed by operation.—Mr. BANKS, Dr. FINEGAN, Mr. LARKIN, and Dr. O'HAGAN also made remarks.

Dr. E. W. HOPE read a short paper on Ice-cream as a Vehicle of Infection in Typhoid Fever. He spoke of the dangers of ice-cream as sold by the itinerant vendor. He had obtained some street-sold ice-creams and had submitted them to Professor Boyce for bacterial examination; these had shown an enormous number of sewage bacteria. Some cases of typhoid fever had been distinctly traced to ice-cream sold at a fair in a suburb of Liverpool. In the future the manufacture of ice-creams would be regulated in the same manner as the milk traffic.—Dr. HILL said he was engaged at the present time in an investigation into the micro-organisms of sewage. He was struck with the marked similarity between plate cultivations of the ice-creams referred to and those of sewage. It was difficult to distinguish between them both from the number and the nature of the organisms present, many being identical in character and appearance.—Professor BOYCE, Dr. BABB, and Dr. LOGAN also spoke on the subject.

Mr. BANKS read a note on the Clamp and Cautery Operation for Hæmorrhoids. He said that he considered the operation a good one and one which was permanent in its results. He also said that he thought Paquelin's cautery if properly cared for a most reliable instrument. He mentioned various small details which he had found useful to the patient in saving pain and to the surgeon in saving time and annoyance.—Mr. ROBERT JONES condemned the clamp and cautery as an implement not in accord with modern surgery; it possessed no advantages over cleaner methods. He had for some years practised a method of suturing hæmorrhoids which promoted rapid healing, rendered bleeding impossible, and saved the patient much pain. Dilatation of the anus should always be performed as a preliminary.—Mr. THELWALL THOMAS had abandoned the cautery for years and now treated hæmorrhoids by clamp, removal of excess, and suturing the stump with a crossed and reef-knotted stitch. The operation was painless and uneventful. Patients were out of bed on the sixth or seventh day. Hæmorrhage could not occur. Forcible stretching of the anus was always used as a preliminary.—Mr. PAUL supported Mr. Banks's contention that properly carried out the operation by clamp and cautery was the most safe, effective, and permanent cure for hæmorrhoids.—Mr. RUSHTON PARKER thought the principal aid to operation and painless recovery was the stretching of the anus.—Mr. BANKS replied.

MIDLAND MEDICAL SOCIETY.

Exhibition of Cases and Specimens.

A MEETING of this society was held on Nov. 17th at the Medical Institute, Birmingham, Mr. J. W. TAYLOR, President, being in the chair.

The following gentlemen were elected members of the society: Dr. H. E. Thompson, Dr. C. K. Millard, Dr. R. W. Briggs, Dr. W. Lamb, and Mr. G. Leonard Hill.

Mr. HEATON showed a girl, aged seven and a half years, whose Left Elbow-joint he had Excised eighteen months previously for extensive tuberculous disease of the joint complicated by peri-articular abscesses. Excision was performed in the usual way. Passive movements of the joints were commenced on the fifth day. At the present time the child could use the arm almost as well as its fellow. The movements of flexion and extension were perfect, but there was some limitation in the power of pronation and supination.

Dr. FOXWELL read a paper on Colitis and showed a married woman, aged thirty-nine years, sent to him by Mr. J. S. Crabbe in illustration of his remarks. In July, 1894, the patient had severe urticaria after taking some tinned rabbit. This was followed by diarrhœa accompanied by tenesmus. This became much worse in November, 1894, and was accompanied by two or three severe hæmorrhages. She was confined to bed for ten weeks and was told that she had typhoid fever. In January, 1895, the diarrhœa ceased and her bowels became irregular and had so continued ever since. The stools were either lumpy and scybalous or else there was diarrhœa. She still passed a good deal of mucus and sometimes the stools resembled the white of an egg. Blood only occasionally appeared, but there was constant tenesmus "even when it was diarrhœa." The patient's bowels had been blocked three times; on the second occasion the obstruction was serious and an operation for its relief was contemplated. Occasionally she could not pass urine for more than twenty-four hours, at other times she had done so every five minutes. She has always been subject to sick headache but had had much more during the last three years. She had lost strength but was fairly nourished and could manage her household duties. There was a dyspeptic redness about the face and the tongue, though clean, was too red. Dr. Foxwell brought her forward as a typical case of non-amœbic colitis; the bowel irregularity, the stools, the fæcal obstruction, the increase of "biliousness," and the acute exacerbation ("typhoid") being all typical of the disease.

Mr. JORDAN LLOYD showed a Suppurating Cyst of the Left Broad Ligament with gaseous contents removed successfully from a woman, thirty-five years of age, about four months after a premature confinement. Her illness began about a week after delivery with multiple joint pains, and as these subsided an abdominal swelling made its appearance without much pain but with irregular septic temperatures. She became anæmic and prostrate, but would not consent to operation until nearly two months after the pelvic swelling had been found and diagnosed. Mr. Lloyd called particular attention to the fact that the tumour was tense and gave a tympanitic percussion note and even when first cut into had the appearance of a distended intestinal coil.

Dr. KAUFFMANN showed a set of specimens of Syphilitic Lesions in the Liver, Lung, and Shoulder-joint, all from the same patient. In the liver there were numerous small gummata, not exceeding a split pea in size and of characteristic appearance to the naked eye and under the microscope. In the lung the lesion took the form of an extensive mass of white fibrous tissue of great denseness, forming a stout solid mass evidently peribronchial in origin and spreading in a radiating manner into the lung tissue. In the shoulder-joint the lesion was considered during life to be of tuberculous nature and this opinion was borne out by the appearance of the joint when opened after death. The clinical points in which the joint conditions differed from the tuberculous suppurative disease were the comparative absence of pain considering the amount of swelling and destruction and the wide ramifications of the abscess along the lines of tendon sheaths in the neighbourhood.

PLYMOUTH MEDICAL SOCIETY.

Exhibition of Cases and Specimens.

A CLINICAL meeting of this society was held on Nov. 20th, Mr. J. E. SQUARE being in the chair.

Dr. FOX showed the following cases:—1. A man, aged forty-two years, in whom Jaundice had suddenly appeared three months previously after a sharp attack of pain. The gall-bladder was distended and the liver was enlarged. It was decided to explore the gall-bladder. 2 A man, aged about forty years, with Obscure Nervous Symptoms most pronounced on the right side. An Argyll-Robertson pupil was noted on the right side and absence of the knee-jerk in the right leg. The ankle of this side had developed (after an injury) large masses of new bone from the

Digitized by Google

lower epiphyses of the tibia and fibula and a thickened elastic condition of the synovial membrane. The joint was not at all flail-like nor did there appear to be any fluid in it.

Mr. WOOLLCOMBE showed a man from whom, for Epithelioma of the Penis with enlarged inguinal glands on both sides, he had removed the entire penis, scrotum, and testicles, bringing the urethra out in the perineum. Both inguinal regions were cleared of glands by means of two horizontal incisions radiating from the central one. The operation was rapid,—it left a wound with no pouches to delay healing—was thorough, and was not followed by any severe shock or mental disturbance.

Mr. J. E. SQUARE showed a girl, aged twenty years, with a Thickened Conjunctival Fold in the Outer Canthus of the Right Eye, from which grew a hair.

Mr. C. E. RUSSEL RENDLE showed a child, aged nine years, who had been a well-marked Cretin but under thyroid extract was rapidly losing the characteristic signs and symptoms.

Mr. ALDOUS showed a boy, aged thirteen years, with a round, raised, and partially pedunculated Swelling three-quarters of an inch above the red margin of the left Upper Lip. The surface was red and crossed by numerous dilated capillaries and exuded a thin, purulent, and sometimes bloody fluid. Beneath the jaw were two or three enlarged and hard glands. About the base of the tumour there was no trace of induration. Three weeks ago the sore was twice the size. He regarded it as a chancre and was treating the case with mercurial inunction. Various opinions were expressed as to its being of sebaceous origin—molluscum, nævoid, &c.—and a cessation of treatment was advised.

Mr. WHITEFORD showed a youth, aged eighteen years, with Syphilitic Sloughing of the Soft Palate and Adhesion of the remains to the Pharynx and Naso-pharynx almost occluding the posterior nares, causing bad phonation and deafness.

Mr. RYAN showed a woman, aged sixty-two years, with nodules of varying size from that of a pea to that of a hen's egg beneath the skin of the Face and Neck, some of ten years' duration. The largest had rapidly grown after a blow three months previously and the skin over it had become discoloured. He regarded them as sarcomata. Other members thought them lipomata and the large one to be undergoing nævoid degeneration.

The following specimens were exhibited:—

Dr. WEBBER: (1) A large Multilocular Ovarian Cyst; (2) a Tongue removed from a woman, aged forty-two years, for Epithelioma; and (3) a Uterus removed per vaginam for early Cancer.

Mr. WOOLLCOMBE: Fourteen Calculi removed from a Kidney. The largest weighed two and three-quarter ounces and the whole number five and a quarter ounces. The patient made a good recovery.

Mr. ALDOUS: Primary Scirrhus of the Head of the Pancreas obstructing the common duct and causing Jaundice.

Dr. BUSHNELL: A slide of Diphtheria Bacilli.

GLASGOW SOUTHERN MEDICAL SOCIETY.

Exhibition of Cases.

A CLINICAL meeting of this society was held on the 18th inst. in the Victoria Infirmary, Dr. JAMES W. ALLAN, President, being in the chair.

Dr. EBENEZER DUNCAN showed a case of Diabetes under treatment with Uranium Nitrate. This drug was introduced into medicine by the homœopaths who got good results with it, probably by using large doses of it. Dr. Samuel West recently brought the drug before the profession.[1] Dr. Duncan made brief reference to his Montreal paper.[2] Since then two cases had been under treatment one—the case shown—being a man who had been ill for eighteen months and having 26·25 grains of sugar per ounce in the urine when admitted to hospital. Beginning with a dose of 5 grains it was gradually increased to 10 grains, when the dose had to be diminished to 7½ grains on account of diarrhœa and then again increased to 10 grains, which dose the patient was then taking with comfort and decided benefit. Previous careful treatment by opium and codeia had made an improvement up to a certain point, relapse immediately following when this treatment ceased. The patient had much improved in health and strength. Sugar was absent from the urine and polyuria and the other distressing symptoms were entirely relieved. The remedy was harmless; no nephritis or gastritis was produced. Diarrhœa might easily be avoided by using a pure salt, reducing the dose if it threatened, and avoiding over-eating. The usual dietetic treatment was adhered to, but all the patients had an abundant supply of milk—two or three pints per diem. The other case mentioned was that of a child who came into the ward feeble and passive but improved so much under this treatment that he became strong and active and so unruly and unmanageable that he had to be dismissed. Dr. Duncan was of opinion that the remedy had a stimulating effect on the sugar-producing cells either directly or through the nervous system.

Dr. DUNCAN also showed a patient who had suffered from a Syphilitic Gumma of the Brain. The patient was a woman, aged forty-nine years, who complained of weakness of the left arm and slight aphasia. There was no weakness in the lower limb. Headache was present. Ophthalmoscopic examination showed congestion of the discs and filling up of the congenital cup. There was a clear history of syphilis dating twenty years back; the patient had had seven still-born children and had had attacks of Jacksonian epilepsy involving the affected limb. Perchloride of mercury and iodide of potassium were given. Then the iodide alone, beginning with a 10 grain dose and pushed to 130 grains three times a day. The signs of the disease quite disappeared but cardiac symptoms developed under the large doses. Nitrite of sodium in doses of 2 grains afforded marked relief from the anginal attacks.

Dr. DUNCAN further showed a case of Chronic Rheumatic Arthritis treated by baths (Schott system) and salophen in gradually increasing doses of cod liver oil, and described various forms of Valvular Disease of the Heart—Enlarged Heart improved by Bath treatment; Double Aortic Disease; and Graves's Disease.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Pneumonia a Multiple Infection.—Pityriasis Rubra.

A MEETING of this section was held on Nov. 19th, Sir G. F. DUFFEY, President, being in the chair.

Dr. J. W. MOORE read a paper entitled Pneumonia, a Multiple Infection, in which he adduced evidence that the micro-organisms peculiar to erysipelas, to influenza, to tuberculosis, and to enteric fever may one and all give rise to a specific pneumonia or pneumonic fever. So also may Löffler's diphtheria bacillus and the bacillus of malignant anthrax as well as other pathogenic bacteria. There is clinical evidence to show that a true pneumonitis may occur in any one of the four diseases—erysipelas, influenza, tuberculosis, and enteric fever; and if it is objected that Eberth's bacilli have not as yet been often found in the lungs or sputum of enteric fever patients this is probably due to the comparative infrequency with which so far search has been made for these bacteria in the pulmonary organs.—Mr. HENRY CROLY said that he had for twenty-four years been familiar with pneumonia as a complication of erysipelas.—Dr. J. W. MOORE, in reply, said that in influenzal pneumonia the specific organism of pneumonia was not often present but the streptococcus pyogenes.

Dr. J. B. COLEMAN read a paper on Pityriasis Rubra, and exhibited a patient suffering from the disease, a man, aged twenty years, who was admitted to the Whitworth Hospital on Nov. 4th, 1897, suffering from general redness and scaling of his skin and from some itchiness. The eruption appeared suddenly last May in the shape of redness on the back of his hands and wrists and within a week his whole body was red and scaly. He had not previously suffered from any form of skin disease and had enjoyed excellent health. The appearance of the affection was attended with no general symptoms. He never had syphilis, but there was a history of alcoholism and of exposure to cold and wet. His family was free from any gouty, rheumatic, or phthisical taint. On admission to hospital he was fairly well nourished though of slight build and he enjoyed good health except for the condition of his skin. He felt chilly when he went out of doors and at night he was troubled with itching. His lungs and heart were healthy, his appetite was good, and his temperature was normal. He had marked leucocytosis, the

Digitized by Google

white corpuscles being increased to 37,000 per cubic millimetre. The eosinophile cells were also relatively increased, constituting 10 per cent. of all the white cells. The urine was normal; the bowels were confined. The axillary and inguinal glands were moderately enlarged. The skin all over his body was dull red in colour and covered with thin papery scales; it felt hot, rough, and dry; he never sweated. The redness faded on pressure and left a yellowish hue. The scales varied in size from branny desquamation on his face to larger flakes as big as a sixpenny-piece on his back and limbs. The scales were thin, whitish, easily separated from the subjacent skin, which was red, but neither moist nor infiltrated. During the earlier months of the disease the scales were larger, and every morning about a pint of scales and powdery detritus was found in his bed. Some of the nails were thickened and loose, whilst others were thin and long. The scalp was covered with whitish-yellow matted scales and the hair was falling out. The epidermis on the palms of the hands was thin (as if newly-formed) and superficially cracked; the skin of the soles was thicker and desquamating. When the skin on the flexor surface of the arms and on the sides of the neck and trunk was relaxed it was covered with fine ridges and furrows which were replaced by red linear streaks when the skin was made tense. The diagnosis of the case, as an example of Hebra's type of pityriasis rubra, depended on the onset of universal redness of the skin, associated with loosely adherent, thin, papery scales and on the absence of thickening, moisture, or of any primary lesion.—Dr. WALLACE BEATTY said that on looking at Dr. Coleman's case for the first time one might think that it was one of generalised seborrhœa, but the history must show that it was a case of pityriasis rubra.—Dr. FINNY said that there were in this case symptoms which he had not seen in any case of pityriasis rubra—namely, great thickening of the scalp with a great quantity of scales and with alopecia. The patient also had to scratch himself and he (Dr. Finny) thought that this was one of the peculiarities wanting in pityriasis rubra as there was generally no itching at all.—Dr. COLEMAN, in reply, said that neither some thickening of the skin nor itching were sufficient to upset the diagnosis of pityriasis rubra; in fact, in some of the very chronic cases a considerable amount of thickening of the skin had been found. Itching had also been noticed in cases now and then as a prominent symptom although not a common one.

Reviews and Notices of Books.

The Dwelling-House. By GEORGE VIVIAN POORE, M.D., F.R.C.P. Lond., Physician to University College Hospital, London: Longmans, Green, and Co. Price 3*s.* 6*d.*

THE main object of this book is to advocate the adoption of the dry method of sewage disposal in preference to water carriage and many of Dr. Poore's arguments have much force. He is an excellent debater and the position he takes up is very strong if not impregnable, but by selecting extreme cases he arrives in one or two instances at some rather startling results. In one case in the opening chapter he reproduces certain plans of the first of two typical London houses examples of which were published in THE LANCET.[1] The various evils, both sanitary and constructive, commonly met with in town houses had been concentrated in this example, for purposes of illustration, though it is to be hoped that few houses exist actually in such evil plight. Had Dr. Poore taken the second example in this report to demonstrate his argument against the excessive cost of existing sanitary methods, his calculations would have more nearly approached a correct average, and his arguments, though apparently robbed of a little force, would have been just as sound.

Dr. Poore is ingenious in his indictments. He holds that the water carriage of sewage and the high pressure system of water-supply tend to overcrowding by facilitating the erection of enormously high buildings to the exclusion of sunlight and of the free circulation of air, the result being damp, gloomy houses and streets filled with the exhalations from sewer gratings and drain ventilators. His remarks upon overcrowding, its causes and its effects, are emphasised by some very unpalatable but reliable statistics, and the Building Acts and by-laws under which model dwelling-houses are constructed (?) come in for their share of censure. The central idea of modern municipalism, in Dr. Poore's opinion, is the raising of loans and the sweating of the ratepayers.

That the water-carriage system is essentially an artificial one is evident and in common with every unnatural process is surrounded with special elements of danger. In London and other great towns existence is, however, more or less artificial throughout. Water as a carrier has obtained such a hold upon public favour and vested interests are so involved in its maintenance that however desirable a change might be there is at present little prospect of any alteration in our larger towns. Dr. Poore appreciates this position, but points out the extreme folly of taking the system of building and the sanitary methods prevalent in London as models for country towns and villages where the environments are altogether dissimilar and where the expedients to which the metropolis has been driven are quite uncalled for. Water carriage for sewage Dr. Poore designates as "spending our money to dissipate our capital" with the added risk of poisoning our water-supplies. He insists upon advantage being taken of the recently discovered fact that the first few inches of cultivated soil alone can break up and assimilate organic matter, the subsoil having no such power. Whatever is buried deeply or escapes from drain or cesspool below the protecting layer of living earth may retain indefinitely its original character and immensely increase the risks of pollution. He recommends the use of the dry earth closet so that the whole of the effete organic matter may be promptly returned to the surface of the land. This closet is not the usual pail closet met with in so-called dry methods in which the urine and fæces mingle but a special arrangement, devised by Dr. Poore, illustrations of which are given.

If a dry method of dealing with sewage were employed the subsoil water, being unpolluted by leaky drains and cesspools, could under such circumstances (as Dr. Poore points out) be collected in properly constructed shallow wells, and thus local water-supplies could be formed. He believes that such local supplies would be preferable, as the putting of all sanitary eggs into one basket which has led to disaster at Maidstone, Lynn, and elsewhere would then be avoided. We are not sure that such local supplies would be an improvement, for they would not receive the same supervision that ought to be, and is supposed to be, given to one main and central supply. The book describes in detail and illustrates the various means to be employed for the disposal of slop water and fæcal and other organic waste. The results of some experiments of filtering urine through sawdust are particularly interesting, as also is the chapter upon the circulation of organic matter and the effect of manure upon garden *humus* under varying conditions of temperature and moisture. Dr. Poore aptly views our modern sanitary methods as savouring "too much of Hercules and too little of Minerva."

Certainly the constantly recurring epidemics should cause rural authorities to pause before adopting, often at vast expense, a system or systems of dealing with their sewage for which in some cases there is no absolute necessity. The reason why former attempts at dry methods have often proved so discouraging is that the systems adopted have not been in conformity with natural laws. Dr. Poore has not only devoted many years to the study of the question but, and this is of equal value, he has superintended its practical application.

With hundreds, nay, thousands, around us stricken down

[1] Report of THE LANCET Special Commission on the Relative Efficiency and Cost of Plumbers' Work, THE LANCET, July 4th, 1896.

Digitized by Google

by preventable diseases, the present subject cannot be dismissed with a few commonplace eulogies upon Dr. Poore's book. Worthing, Maidstone, Lynn, and Clifton are neither better nor worse than hundreds of other towns in which the elements of danger are present and are only waiting the moment of conjunction to develop similar or even worse disasters. Instead of passively following models that are not always good, and when good by no means always suitable, it surely would be better if sanitary authorities carefully investigated without prejudice every rational suggestion for the amelioration of existing dilemmas. Dr. Poore's book is an eloquent little plea for such practical open-mindedness.

Handbuch der Therapie innerer Krankheiten. Herausgegeben von Dr. F. PENZOLDT und Dr. R. STINTZING. Zweite Auflage. Lieferungen 1, 2, und 3. (*Handbook of Treatment of Internal Diseases.* Edited by Dr. F. PENZOLDT and Dr. R. STINTZING. Second edition. Parts 1, 2, and 3.) Jena: G. Fischer. 1897. Complete in seven volumes. Price 105*s.* by subscription.

THE first edition of this encyclopædic undertaking has been barely completed before we have to notify the issue of the first three "Lieferungen" of the second edition. The original publication appeared in somewhat piecemeal fashion, each "Lieferung" mostly containing portions of one or more of the seven bulky volumes that made up the whole work; but this re-issue will proceed in more regular fashion. The work opens with the subject of the Infective Fevers and measures of general prophylaxis are described by Dr. A. Gärtner and those of General Therapeutics by Professor von Ziemssen, Dr. Buchner writing upon protective inoculations. Amongst the special articles that on Small-pox and Vaccination by Dr. L. Pfeifer is most noteworthy; it contains a description of the author's discovery of protozoal organisms in variola. The subject of vaccination is fairly and thoroughly dealt with. In the discussion of other infectious diseases the serum treatment naturally receives much attention, Dr. von Ganghofner writing on Diphtheria and Dr. Th. Rumpf, of Hamburg, on Asiatic Cholera. The latter article is very full and contains much valuable information, the prophylaxis being especially dwelt upon. With regard to the treatment of Typhoid Fever (Professor H. von Ziemssen) cold or tepid bathing is strongly approved, the recommendat on being made to commence the treatment in the early stages of the fever, the baths at first being tepid. The volume closes (in the third "Lieferung") with articles on the treatment of affections of the ear and eye arising in connexion with specific fevers. The second volume opens with such "disorders of metabolism" as corpulency, diabetes, and gout. The work is well-known and evidently much appreciated and the second edition brings the publication well up to date.

Reference Book of Practical Therapeutics. By Various Authors. Edited by FRANK P. FOSTER, M.D. In two volumes. London: Smith, Elder, and Co. 1897. Price £2 10*s.*

THIS is an elaborate work in two volumes containing a vast amount of information on practical therapeutics. The editor states in his preface that the leading idea in the preparation of this work has been to make it pre-eminently serviceable to the practising physician. It is not intended to take the place of treatises on materia medica or on pharmacy, hence as regards the physical properties of drugs, their mineralogical, chemical, botanical, or zoological relations, &c., the endeavour has been to set down only so much as is of direct bearing on the use of those drugs in medical practice or on the management of poisoning due to them. In all these matters the writers who have assisted Dr. Foster have been most successful. Even accounts of the physiological actions of drugs are condensed, for much of what the experimental pharmacologist justly looks upon as essential to the prosecution of his studies is useless and clogging superfluity to the physician in the daily work of treating the sick. For the same reason profusion of references to literature has been avoided. With one exception (Dr. Gordon Campbell, of Montreal) all the contributors are American.

The various drugs and methods of treatment are arranged alphabetically so that the work forms a dictionary very easy of reference. The articles are on the whole well written and the information full and reliable. For instance, the article on Cinchona, by Dr. Henry A. Griffin, of New York, is an admirable description of the various forms of cinchona barks and their uses. Another contribution—namely, that on Exercise, by Dr. Henry Ling Taylor—is also valuable, containing as it does a full consideration of the functions and needs of the neuro-muscular apparatus of the body and the importance of gymnastics and other forms of regular exercise in the training of children. A kindred subject, Massage, is ably dealt with by the same author.

Some of the articles, however, are written in rather too dogmatic a form. We may take, for instance, that on Hydrocyanic Acid by Dr. J. T. Whittaker. The effects of poisoning by this substance and the methods of treatment and antidotes employed in combating an overdose are certainly well described, but we think that general opinion would be against the following sentiments: "Hydrocyanic acid has little or no medicinal virtue and should, on account of its danger (*primum non nocere*), be banished from the shop of the apothecary and the pages of the materia medica. It had formerly a reputation as a sedative and was often prescribed, especially with morphine, for the relief of nausea and pain in the stomach. It is very questionable, however, if it possesses any such virtue."

A most interesting contribution is that by Dr. Austin O'Malley, of Washington, on Serum Therapy. Much care has evidently been expended in collecting the material needed and all the latest knowledge and experience in this newest branch of therapeutics are concisely recorded. The work certainly supplies a want and can be recommended to our readers.

LIBRARY TABLE.

Descriptive Catalogue of the Pathological Museum of St. Mary's Hospital. (Additions, 1891–1897.) By J. JACKSON CLARKE, M.B. Lond., F.R.C.S. Eng. Morton and Burt, Printers. 1897.—The value of a museum depends very largely upon the care which is bestowed on the preparation of a descriptive catalogue and Mr. Jackson Clarke is to be congratulated on the thoroughness and care with which the present addendum to the catalogue of the St. Mary's Hospital Museum has been prepared. Amongst the specimens described are many of great importance. No feature of our London hospitals is more striking to the foreigner than their pathological museums, and we have just reason to be proud of them, not only for their intrinsic value, but for the care which is displayed in the cataloguing and description of their contents. The present volume is clearly printed and well arranged and short clinical abstracts are in most cases appended to the descriptions of the specimens adding much to their value.

On the Employment of Itrol (Citrate of Silver) in the Treatment of Gonorrhœa. By Dr. O. WERLER. *On the Treatment of Venereal Ulcers with Itrol.* By Dr. O. WERLER. Berlin: S. Karger.—These are reprints from the *Dermatologische Zeitschrift.* The author claims that in gonorrhœa itrol has an intensely destructive effect on gonococci and that solutions of it are well borne by the urethra and cause neither irritation nor any increase of the inflammatory

Digitized by Google

symptoms, also that it has an energetic penetrating power without damaging the mucous membrane and that it therefore fulfils all the necessary indications for the modern treatment of gonorrhœa. In venereal sores he says that owing to its bactericidal energy, its desirable effect, and deep action it soon brings the destructive process to a standstill and rapidly reduces the chancre to the condition of a healthy sore. Dr. Werler says that it is absolutely without smell, makes a clear solution, and produces only slight smarting when applied. It is also very likely to prevent secondary affections of the inguinal glands such as virulent suppurative buboes.

Transactions of the Pathological Society of London. Vol. XLVII. London: Smith, Elder and Co. 1896.—The matter contained in the present volume of these transactions is sufficiently familiar to our readers to absolve us from the necessity of any detailed notice. The value of the communications shows no falling off in merit and the Transactions remain an indispensable work of reference for pathologists. The feature which strikes us as especially noteworthy is the great and increasing excellence of the illustrations which form so valuable and essential a part of the work. For this of course the many advances in the processes for the mechanical reproduction of photographs and coloured drawings are in part responsible but much credit is due to the enterprise of the Pathological Society in making such liberal use of them.

The Edinburgh Medical Journal. New Series. Vol. I. Edinburgh and London: Young J. Pentland. 1897.—The first volume of the new series of this well-known monthly periodical shows that its high standard of excellence is fully maintained. In spite of its title we note that a very fair proportion of its original articles are from the pens of writers south of the Border and indeed this is as it should be. A judicious admixture of writers from various "schools" should not only secure a wider circle of readers but also—and this is more important—act as a check to the tendency to exclusiveness which must inevitably beset the teachings of any particular school. Amongst the original contributions are many of a very high order of interest and importance. The reviews are by able and critical writers and the monthly accounts of recent advances in medical science are of great excellence. The volume as a whole is well printed and attractive and forms a valuable addition to a medical library.

The Leisure Hour still maintains its high standard of excellence and in the December part just issued will be found many articles of interest. The Science and Discovery section is a useful one.

The current issue of the *Girls' Own Paper* contains several seasonable articles. There is also a full-page reproduction of a portrait of the late Duchess of Teck. The Christmas extra number of this publication *Christmas Chimes* will no doubt find, as it deserves to, a place at many a Yule ingle-side.

The Sunday at Home is full of good reading suitable for the purpose which the title of the magazine suggests. The frontispiece, "Nothing venture nothing have," is a good reproduction after the picture by Mrs. Alma Tadema.

DIARIES.

Messrs. Letts's Diaries (Cassell and Co.) are so well known and highly appreciated that it is scarcely necessary to do more than call attention to the fact that those for the new year fast approaching are now ready, and that, as usual, the series comprises books to meet almost every individual requirement, at prices varying from 6*d.* to 16*s.* The "Medical Diary" is ruled for noting obstetric engagements, vaccination, nurses' addresses, thermometrical and other fluctuations, monthly cash account, &c., and contains in addition much useful information expressly compiled for the profession. Another very useful publication of Messrs. Letts is the "Medical Prescription Copyist," by means of which prescriptions can be made out in a uniform style and a copy of each kept for future reference.

Messrs. Rudall, Carte, and Co., of 23, Berners-street, send us their *Professional Pocket Book and Hourly Engagement Diary.* The diary is divided into three parts of four months each, a convenient arrangement which reduces the size of the book to be carried, as of course only one part need be carried at a time. The three portions are contained in a neat leather case, and although the diary is primarily intended for the professional musician its arrangement will make it useful for any busy man whatever be his calling.

Analytical Records
FROM
THE LANCET LABORATORY.

SOLOIDS FOR USE IN GYNÆCOLOGY.

(BURROUGHS, WELLCOME, AND CO., SNOW HILL BUILDINGS, E.C.)

THE following formulæ have recently been adopted by Messrs. Burroughs, Wellcome, and Co. in soloid form. 1. Sodium biborate compound, each soloid containing 20 grains of sodium biborate and 10 minims of tincture of opium. 2. Alum compound, each soloid containing 15 grains of zinc sulphate and 15 grains of alum. 3. Zinc and tannin compound, each soloid containing 5 grains of sulphate of zinc, 10 grains of lead acetate, 2 grains of extract of opium, and 1 grain of tannin. In this last formula obviously the zinc sulphate will when the soloid is placed in water react with the lead acetate to form acetate of zinc in solution and a precipitate of sulphate of lead. The resulting zinc acetate would then yield a zinc tannin compound. The object of these soloids is to enable the practitioner to prepare solutions for irrigations in gynæcological practice.

FALONA.

(THE FALONA FOOD AND CEREAL CO., 15, SEETHING-LANE, E.C.)

Falona is described as a combination of dried vegetables and cereals. We found it to contain more than one cereal, but of the existence of vegetables we cannot speak. It has a very pleasant malty flavour and yields when suitably prepared an undoubtedly nourishing food. This appears from our analysis which is as follows:—Moisture, 10·88 per cent.; mineral matter, 2·11 per cent.; organic matter, 87·01 per cent. The organic matters consist as follow:—3·40 per cent. fat, 12·81 per cent. nitrogenous substances, and 70·85 per cent. carbo-hydrates. It is thus, in addition to the digestible character of the carbo-hydrates consequent chiefly on careful cooking, rich in fat and in mineral matter, the latter consisting largely of phosphates.

VINOLIA PRODUCTS.

(BLONDEAU ET CIE, MALDEN-CRESCENT, LONDON, N.W.)

According to our examination the Vinolia preparations consisting mainly of articles for toilette use afford distinct evidence of the endeavour of these manufacturers to use only innocent yet effective ingredients. This is the only point which interests us in regard to such preparations. We have not found a single injurious constituent in any one of the new preparations recently submitted to us. An enormous advance has been made in the preparation of soaps, hair-washes, powders, shaving materials, &c., during the last twenty years, a fact which has contributed not a little to the comforts and sanitary conditions of modern life. Of new preparations recently submitted to us we may mention three soaps respectively entitled "buttermilk," "lilac," and "heliotrope," each of

Digitized by Google

which carries its own distinctive yet delicate scent. They contain nothing but bland soap and are free from any resinous matters or trace of free alkali. Vinolia violet powder is very finely divided and in addition to this desirable condition is a harmless antiseptic. Another preparation worthy of notice is the Vinolia dry hair wash. It is of course a spirituous fluid which yields on evaporation a delicate lather but without stickiness. It is satisfactory to find that articles of the quality described may be obtained at quite a moderate figure.

DIABETIC BROWN BREAD.

(CALLARD AND CO., 65, REGENT-STREET, W.)

Despite the entire absence of farina and sugar in this sample it is pleasing both in appearance and to the taste. It is desirably moist and keeps for some days without getting stale. We have tested the bread thoroughly. It can hardly be distinguished from the ordinary brown loaf when partaken with butter or when toasted.

AMBER ALE.

(THE ANGLO-BAVARIAN BREWERY, LIMITED, SHEPTON MALLET, SOMERSET.)

The specific gravity of this ale proved to be 1010 observed at normal temperature. This is the first indication of a malt liquor of a light character. Further results confirmatory of the foregoing were as follow: alcohol, by weight 4·62 per cent. by volume 5·78 per cent., equal to proof spirit 10·13 per cent.; extractives, 3·95 per cent.; mineral matters, 0·26 per cent., containing abundance of phosphates; acidity reckoned as acetic acid 0·02 per cent. The ale possesses a delicate bitter taste and as the results show is of comparatively low alcoholic strength. It was in perfectly sound condition, of a pale colour, and free from objectionable preservatives. It therefore accords with the definition of pure beer—that is, a liquor brewed from malt and hops.

OKOL.

(THE SANITAS CO., LTD., BETHNAL GREEN, E.)

Okol is a creamy fluid mixing in all proportions with water and forming a milky mixture which has a very pronounced smell of coal tar acid derivatives. It is said to be non-poisonous when used with ordinary care which means of course that it is poisonous but very much less so than carbolic acid. It is decidedly alkaline to test-paper and on acidifying the fluid with hydrochloric acid the separation of oils is evident. In regard to its antiseptic and germicidal properties it compares favourably with allied preparations. According to Dr. Rideal this preparation is far more active than is carbolic acid in the same weight.

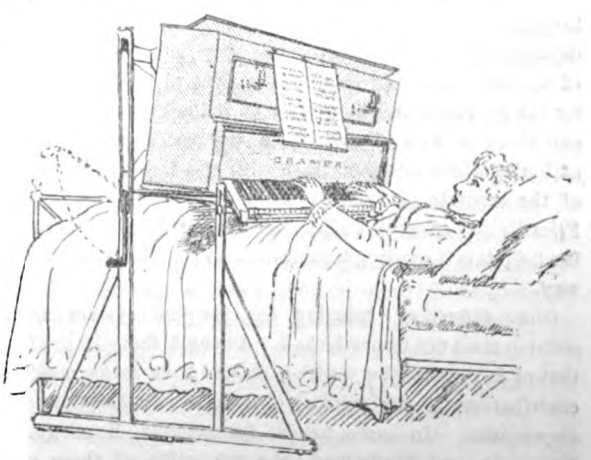
ONOMOSTO.

(THOMAS GRANT AND SONS, MAIDSTONE.)

As the title of this sparkling beverage would imply it is made solely from pure grape juice. This is fully confirmed by our analysis, which is not different from the results obtained with many high-class champagnes. It was as follows: alcohol, by weight 9·50 per cent., by volume, 11·79 per cent., equal to proof spirit 20·65 per cent.; extractives, 4·10 per cent.; mineral matter, 0·15 per cent.; fixed acids reckoned as tartaric, 0·63 per cent.; volatile acid reckoned as acetic acid, 0·07 per cent.; grape sugar, 3·58 per cent. The specimen contained no objectionable preservatives. Its flavour was of that agreeably dry character esteemed in champagne of good quality. It is evidently prepared with the greatest care or otherwise the delicate fruity and pleasantly acid flavour of the juice of the grape would not have been so successfully retained. As will be seen from the above analysis the wine is of the same alcoholic strength as champagne. The small amount of acidity both free and fixed is another commendable feature. It is a sound exhilarating beverage and pleasantly sparkling and compares favourably in regard to its pleasing qualities with similar sparkling but much more expensive wines. It is quoted at 24*s.* per dozen champagne quarts.

New Inventions.

A NEW VAGINAL TUBE.



WITH a view to improving on the red gum-elastic tube that is almost universally used for vaginal douching I have devised one that is intended not only for simple hygienic self-douching, but which will be found to be of considerable advantage under all circumstances where it is necessary to apply antiseptic solutions to the walls of the vagina. The tube is seven inches long and rigid; its "business" end is bulbous, sufficiently so to allow facile introduction and withdrawal, yet of such size as will dilate each portion of the vagina as it is passed. It can be made of vulcanite or any rigid material that will bear the action of solutions. Those made for me by Messrs. Arnold and Sons are of vulcanite. The bulbs are of three sizes, the largest being used after parturition or where the vagina is particularly roomy. This form of tube may be manipulated into each fornix freely and fearlessly, and however clumsy a patient or nurse may be no harm can possibly be done to the parts. Rigidity enables the manipulator to douche out all folds, even if the size of the bulb is not of itself quite sufficient. The end is bulbous in order to dilate each successive portion of the vagina as it is passed, though it permits a ready outflow behind it, while complete collapse of the vaginal walls takes place upon the thin stem so that no air is admitted. The holes are made at the extreme end of the bulb and not on the periphery. The small end is made to fit the ordinary bone rectal tube that accompanies all enema syringes.

Buckhurst-hill. HAYDN BROWN.

A PIANO FOR INVALIDS.

THE illustration which we give below sufficiently explains itself. Messrs. Cramer and Co. are the designers of the small portable piano which thus slung from a frame across the patient's bed enables the bed-ridden musician to pursue

his or her art. We are indebted to Dr. Frederick Spicer, of Devonshire-street, Portland-place, W., for the sketch which we reproduce and think it probable that many invalids may like to avail themselves of the opportunity afforded by this little instrument of whiling away weary hours.

THE LANCET.

LONDON: SATURDAY, DECEMBER 4, 1897.

THE outspoken series of articles on the subject of the abuse of hospitals contributed by our Special Commissioner shows the prevalence of hospital abuse throughout the provinces while the same evil is rampant in London, where deception is rendered easier by the immense size of the population. London has not only its own special liabilities to hospital abuse but it is the refuge of those who find abuse not so easy to practise in provincial towns. Such people, usually of a somewhat mean nature to begin with, find an easy excuse for themselves and others either in the supposed importance of their cases or the just charges of their local physicians and surgeons for transferring themselves to a London hospital where the operation or the advice that would cost them a reasonable fee in their own town is to be had for nothing. This is the essence of the forbidding story that our Special Commissioner has told with wonderful consistency despite its variety of illustration and we are glad to notice a very general feeling that "something must be done." The Hospital Sunday Fund, instigated by a report of its Distribution Committee, has after long delay and hesitation determined to face the out-patient question and at the annual meeting of its constituents will ask for a rule enabling it to regard the presence of an efficient officer to inquire into the fitness of out-patients as a "merit" in a hospital. This is perhaps a very small remedy for meeting such a gigantic evil but it is a step in the right direction, while those who have pressed for some action must now watch its efficiency and report in case of any defect. The Charity Organisation Society has been indefatigable this year in keeping the subject of hospital abuse in the out-patient departments to the front. There may be some differences of opinion about the details of a Central Hospital Board for the guidance and assistance of individual hospitals, but one thing is sure—that will be the best form of central authority which interferes least with the individual freedom of the separate institutions while correcting gross abuses. Friendly and effective coöperation must take place between the hospitals if existing troubles are to be alleviated in this way.

Other influences bringing our hospital system under revision must not be overlooked. Amongst these is the fact that of late years the working classes have made material contributions to our medical charities—both hospitals and dispensaries. In some towns—for example, Birmingham, Newcastle, and Sunderland—the proportion of these contributions to the whole expenditure has become considerable. This is as it should be. But out of this circumstance has arisen a new demand quite clearly unjust. The demand is, in plain English, that the contributions of the working classes shall constitute a claim to attendance—in other terms, that the word "charity" shall be deleted from the vocabulary of hospitals and that everybody who has contributed a few pence or a few shillings in some more or less systematic way to the fund for the support of hospitals and dispensaries shall be entitled to a *quid pro quo* in the form of treatment for any and all ailments that may befal him or his family. This demand must be sternly resisted. A workman's contribution to medical charities no more entitles him to personal treatment than the subscription of the Duke of WESTMINSTER to St. George's Hospital entitles his Grace, his family, and servants to treatment as in- or out-patients of the hospital. To argue the contrary would exhibit a desire to convert our hospitals into provident dispensaries and give a mean character to subscriptions meant for the benefit of those who are the subject of exceptional disaster or disease. If the claim to make the hospital an open surgery for everybody who likes to go and who has paid a few small fees to its support is to be allowed it requires little foresight to see that the generous gifts of the unselfish will be promptly withdrawn in favour of other charities that restrict themselves to helping those who need help—those people, in fact, whose benefit was originally contemplated by the founders of hospitals.

The most memorable fact in hospital history during the Diamond Jubilee year is one which promises to have lasting influences on the hospital system—we mean, of course, the PRINCE OF WALES'S Hospital Fund for London. The kindness of the PRINCE'S nature and the beneficence of HER MAJESTY'S reign could have no better illustration than the one supplied by the PRINCE OF WALES'S Hospital Fund. As the time approaches for the dispensing of the Fund all friends of sound hospital charity have become deeply interested in the principles that will be employed in the distribution. We venture to believe that the PRINCE OF WALES and his Council may be safely trusted to see that no fantastic experiments and no crude theories will be sanctioned in connexion with this Fund. It is the outcome of the joint loyalty of the rich and the poor. Both must be credited with equally unselfish motives in their contributions. As a means of lightening the burden of real hospital work—work done for the genuine poor—the Fund will be invaluable but as an object for new-fangled experiments it may be worse than useless. The PRINCE OF WALES may do as much good by insisting upon principles of distribution in accordance with his own good judgment as he has done by the creation of the Fund itself.

SIR RICHARD THORNE'S inaugural address to the Midland Medical Society on Soil and Circumstance in their Control of Pathogenic Organisms, which appeared in THE LANCET of Nov. 6th, will have been read, we know, with particular interest, coming as its views do from the highest official sanitary authority in the land. To put the matter shortly Sir RICHARD THORNE points out that places and persons equally show a predisposition to, or immunity from, certain diseases; in other words, that specific infections continue to retain their vitality in certain localities so that diseases are found to haunt these spots. "I have known," he says, "a house standing in large grounds to be smitten with enteric

Digitized by Google

fever on three different occasions, the disease affecting in succession three different sets of tenants; and although between the second and the third occurrence the dwelling had been untenanted for nearly two years yet the disease reappeared amongst the new tenants within a few weeks only of their occupation of the dwelling." We may feel perfectly sure that all the ordinary defects of drainage and water-supply were absent in this house, for otherwise Sir RICHARD THORNE would not have adduced the instance as proving anything; but in view of the two years' rest given to the polluted environment it would be interesting to learn the results of a bacteriological examination of the soil.

To examine the soil to find bacteriological reasons for epidemic diseases is an eminently practical proceeding and we learn from Sir RICHARD THORNE that Dr. SIDNEY MARTIN has been conducting a series of such experiments for the Local Government Board, his attention being specially directed to the power of certain sterilised soils to maintain the vitality of the bacillus typhosus artificially implanted into them. The result of Dr. MARTIN'S experiments with these soils is that in a soil "organically polluted" the bacillus typhosus not only lived for over nine months but increased; while in two samples of virgin soil, one peaty and the other sandy, the vitality of the bacillus extended to twenty-three days at the utmost. Of course the conditions under which these experiments were made do not exist in nature, but the results are none the less suggestive, and we see no difficulty in admitting the possibility that the bacillus typhosus may live in soil even in the presence of millions of saprophytic enemies. Sir RICHARD THORNE uses the words "organically polluted" to apply particularly to soil sodden with the soakings of midden privies such as are common in the tiny back yards of the midland towns, and we do not gather that he anticipates any danger from an open field which is richly manured and skilfully and properly tilled. He says: "Where open spaces about dwellings are large, and where organic pollution of surface soil is practically absent, we may rely, as inhibitive of this bacillus, on the influence of sunlight and of alternating weather; but in our towns the conditions have become too artificial and the open area about dwellings has become too restricted for us to hope that, under the unnatural conditions which have been induced by urban aggregations of dwellings, we have any right to expect the full benefit of nature's remedies." It is to be hoped that Parliament will some day see the folly of allowing houses to be built in such a way that the necessary befoulings which are part and parcel of our existence have no chance of being remedied by natural processes. Dung of all kinds should go to the soil, but there seems to be some danger of this common fact being forgotten in the present day.

WITH the prospect of a meeting of Parliament at an early date next year the question of a Teaching University for London is again being actively revived. The scheme for a reconstitution of the existing University so that it might be at the same time an Imperial Examining Board, as it is at present, *and* a teaching university to satisfy the needs and aspirations of the London students and their teachers, was given up by the Government last session in consequence of threatened obstruction. The scheme was introduced too late and abandoned too quickly. The Government cared little about it and only introduced it because of the recommendations of the Cowper Commission, yet the necessity for a teaching university in London is so obvious and the educational advantages to be derived from its establishment are so great that we wonder at the apathy towards the movement that was displayed by the Government as well as by the London citizen and his representatives in Parliament. For fifty years attempts have been made to establish such a university in London—one whose teaching character should not deprive it of Imperial functions. In 1857 the degrees of London University were thrown open to all persons resident in the United Kingdom without reference to their place of education or to attendance upon any regular course of instruction except—an exception of vital importance at this moment—to persons intending to graduate in medicine for whom a very definite course was, and must be, laid down. In 1863 the Charter was still further widened so that the University had power to confer degrees upon all persons whether resident in the United Kingdom or abroad, but again medical degrees were made the subject of exception, a definite course of medical education being absolutely laid down. In the next year Convocation appointed a special committee to draw up suggestions for the University to undertake teaching functions and from that date to the present the controversy as to teaching and examining or examining alone has been going on.

Twenty schemes for the settling of the question have been fruitlessly brought forward and the twenty-first has been submitted to us and other journals recently for consideration. This latest scheme aims at obtaining the grant of a Charter for a proposed "University of Westminster" in every way separated from the University of London. The new university is to be a metropolitan teaching university whilst the existent institution is to continue its duties as an Imperial Examining Board. The plan of two universities in London—one teaching and examining and the other examining only—was the central idea in the Albert or Gresham scheme, which scheme did not obtain the favour in Parliament which it had met with before the Privy Council and was finally thrown over by the Cowper Commission. We can quite see the conveniences of the plan which provides for two universities and comprehend the view which considers it the real and proper solution of the question but we think that the proposed "University of Westminster" would follow its "Gresham" predecessor into the abyss of lost causes if any attempt were made to carry its academic proposals into reality. It would therefore, to our thinking, serve no practical purpose to discuss the scheme in detail but its promoters—all, we believe, medical men—have done good service by their action for every action is useful that accentuates the needs of the London medical student. It is vital to the London medical student that the same facilities should be given to him that are given to the medical students of other great cities for obtaining a medical degree.

The Duke of DEVONSHIRE, speaking on Tuesday night last at the anniversary dinner of the Royal Society, expressed

Digitized by Google

his hope and trust that at no distant date the Government might be able to make proposals and submit measures for—among other things having an educational bearing—the creation of a teaching university in London. The Duke of DEVONSHIRE is a highly responsible statesman, and we believe that we can read into his words a guarantee that when the Bill dealing with the reconstitution of London University is introduced into Parliament the time chosen will not again be the last moment of the session. We would therefore ask the promoters of the "Westminster University" scheme to be very chary of doing anything that might be or appear to be in conflict with the Government's action for this might lead to another shunting of the whole question. The provisions for the promotion of a Faculty of Medicine are far more satisfactory in the "Westminster University" scheme than are those in the University of London Bill of 1897 and might with advantage be introduced as amendments to that Bill.

Annotations.

"Ne quid nimis."

"WALLACE-ISM."

AT an inquest held not very long since the jury returned the following verdict: "The deceased man died from cardiac failure produced by a poisonous dose of aconite contained in a bottle labeled Wallace's specific, No. 1." As a sequel to this finding the Treasury instituted a prosecution against Wallace, who is described as "a homœopathic practitioner." Upon conviction he was fined in all £20 12*s.* for selling a poisonous drug to a person not known to him without inquiry, without entering the fact of such sale in a book, and without being a chemist registered for the sale of such drugs. On that occasion Dr. Luff, one of the official analysts to the Home Office, deposed that an ounce bottle contained $\frac{1}{2}\frac{1}{7}$th gr. of aconitine, and that a sixth part of an ounce might prove fatal. On Nov. 12th a second Treasury prosecution also resulted in a conviction and the sum total of the fines amounted to £62 16*s.* The so-called "Specific No. 1" is a patented medicine, prepared according to the specification which was submitted to the Patent Office on March 3rd, 1897, and accepted on May 1st, 1897. In this specification the following statement occurs: "It [the invention] consists of a new method of preparing a watery alcoholic tincture of any part of the plant called aconite, which shall retain its curative physiological properties without the greater part of its toxic elements. The chief poisonous alkaloid or principle of aconite is aconitine, and by the method of preparation hereinafter to be described its toxic properties are wholly, or in great measure, eliminated whilst its curative value remains." For the defence it was alleged that the method of preparation ensured the destruction of aconitine or its being broken up into comparative harmless substances, and in support of this contention direct evidence was given by Mr. Wynter Blyth, public analyst to the parish of St. Marylebone, who stated that as a result of his analysis he found 0·09 gr. of an alkaloidal residuum from an ounce bottle of the specific, that this residuum had a bitter taste, and reduced the salts of silver, characters not possessed by aconitine. He concluded that the residuum was a mixture of benzoil-aconine—a very small portion of *aconitine* and a little aconine. There was about $\frac{1}{1}\frac{1}{0}\frac{1}{0}$ gr. of aconitine in the one-ounce bottle. The results of Dr. Luff's analysis varied from those of Mr. Blyth to a singular degree. From an ounce bottle examined in January, 1897, he extracted $\frac{1}{2}\frac{1}{7}$ gr. of aconitine. From an ounce bottle analysed in July, 1897, he obtained $\frac{1}{2}\frac{1}{5}$ gr of aconitine; whilst from a like quantity of the "specific" made by him according to the specification the yield of aconitine was $\frac{1}{2}\frac{1}{0}$ gr. Dr. Luff has had almost unrivalled experience in the study of the chemical nature and other properties of aconitine and his official position is a warranty of his scientific attainments and reliability. It is, moreover, remarkable that the results of his three analyses should have so closely coincided, the quantity of aconitine to the ounce varying only from $\frac{1}{2}\frac{1}{0}$ to $\frac{1}{2}\frac{1}{7}$ gr. As there is no known trustworthy chemical test for aconitine Dr. Luff resorted to physiological experiment. He found that $\frac{1}{7}\frac{1}{0}\frac{1}{0}$ grain of the alkaloid extracted from the contents of the ounce bottle of the "specific" killed a mouse in eighteen minutes with the symptoms of aconitine poisoning. To check the results of the experiment he at the same time injected into another mouse of the same weight and the same species the same weight of ordinary aconitine. The animal succumbed in the same time and in like manner as the other. It is not necessary to call into question the results obtained by Mr. Blyth to prove the accuracy of Dr. Luff's deductions. It is quite possible to accept both as substantially correct. Such a course would, however, lead to the conclusion that the contents of the different bottles of the "specific" varied enormously, and to a degree which showed that no reliance could be placed in the alleged composition of the contents of a particular bottle offered for sale to the public; that in fact the so-called remedy can be looked upon in no other light than as a mixture dangerous to human life. To contend that the Patent Office approved of the specification, and that, too, without objection from the Pharmaceutical Society, goes for nothing in extenuation. The patent was granted on the assumption that the mixture did not contain the poisonous properties of aconite, and any inaction on the part of the Pharmaceutical Society cannot be taken even as a tacit admission of the harmlessness of the "specific." The public need protection and we heartily congratulate the Home Office on their thorough exposure of a miserable piece of quackery and illegality.

ABUSE OF MEDICAL CHARITY IN THE UNITED STATES.

AN American correspondent writes to us: "The question of dispensary and hospital abuse is being raised again in New York City. Although by the refusal of the governor of the state to sign the Bill presented in the spring of this year for the purpose of remedying the existing condition of affairs the hoped-for reforms received a set back it is tolerably certain that this will be but temporary. A very large majority of the medical practitioners of New York are in favour of a radical change in the methods of conducting the hospitals and dispensaries and are determined to leave no stone unturned to gain their object and there can be no doubt but that their efforts in this direction will be crowned with success. On the other hand, it may be said that there is no real desire on the part of the managers of the hospitals and dispensaries to remedy the evil; in fact, it is to their advantage that the present system should continue, so that it is practically a fight between the hospital boards on the one side, who wish things to remain *in statu quo*, and the outside practitioners on the other side, who desire reform. There is a similarity and at the same time a wide difference in the abuse prevailing in the hospitals of London and New York, and this statement can be further applied to such institutions in America and Great Britain in general. So far as the dispensaries and the out-patient departments of the hospitals

Digitized by Google

are concerned the grievances of the medical men in both countries are almost identical—in fact, the conditions in this respect are more or less alike in all the large towns of the civilised world. It is in the internal economy of the hospitals that most of those in the United States differ so widely from those of Great Britain, and the abuses rampant in the in-patients' departments of the two countries are of a totally different nature. In Great Britain people sponge on the charity of the in-patients' department in the same way as they do upon the out-patients' department and the dispensaries. That is to say, persons who can afford to pay for medical attendance pose as paupers and under that guise receive the benefits of a charity intended only for the poor. In the United States, on the contrary, the hospitals for the most part having no income from invested property are compelled in order to keep their wards open to charge the majority of their patients. Some, indeed, are even too poor to admit any but those who can pay, hence there is a disposition to conduct these institutions on a wholly commercial basis and to make charity play but a secondary part. The question asked of a would-be inmate is not how poverty-stricken he is but how much he can afford to pay, and room can seldom be found for a non-paying patient when there is the opportunity of receiving a paying one. To such lengths has this pay system been carried that it is at the present time a serious and growing scandal. Some of these hospitals appear to be fitted up rather as medical and surgical boarding-houses than for the purpose for which they were originally intended. Rooms in them are let at rents from £3 to £10 weekly. The most galling feature in connexion with this system to the medical profession is that the hospital medical officers cannot claim payment from these rich patients and in many instances are compelled to do the extra work for little or nothing, so that what should be their legitimate fees are diverted from the medical staff and the general practitioner is in a worse case as he gets neither advertisement nor money."

SMOKE IN SALFORD.

MANCHESTER and Salford, more especially the latter, suffer much from black smoke and though efforts have been made for many years to prevail upon the authorities to insist on its diminution both towns are still grievously afflicted. It is difficult to convince corporations that smoke is an evil and to induce them to make any earnest efforts for its abatement. Even in these days the amount of smoke is looked on by many as a measure of the activity of trade, and it is more than tolerated on the plea that too much interference would drive industries out of the town, the fact being forgotten that the smoke itself puts great difficulties in the way where any of the numerous occupations requiring cleanliness are carried on—such as the manufacture and manipulation of light and delicate fabrics. It is pleasant, therefore, to know that the other week a deputation from the Manchester and Salford Sanitary Association and the Smoke Abatement League was well received by the Mayor of Salford, when a memorial was presented which stated that it was thought the time had come when "more active steps should be taken by your health committee in the suppression of the smoke nuisance"; that on account of "undue indulgence" the air of Salford was more polluted than that of Manchester and that the latter suffered from Salford smoke over which it had no control. The memorial urged the assimilation of the Salford procedure in respect of the smoke nuisance to that of Manchester. It was signed by Professor Leech, chairman, and by the honorary secretaries of the Sanitary Association, and by Mr. Johnston, chairman, and Mr. Fred Scott, general secretary, on behalf of the Smoke Abatement League. Professor Leech spoke of the great difference between Manchester and Salford as to the regulations concerning smoke and of smoke being one of the factors in bringing about the "frightful mortality" which still prevailed. Mr. Johnston, as an engineer of many years practical experience, said there was no difficulty in dealing with smoke without any injury to manufacturers. Dr. Hutton dwelt on its injurious effects in cases of phthisis and chest diseases and said it was a painful thing to tell people whose livelihood depended on their employment in the great towns that they must live elsewhere. Mrs. Hopwood, of Hopwood, who has been remarkably energetic and successful in her own neighbourhood in efforts for the diminution of the smoke nuisance, said that in Middleton, Castleton, Heywood, and Chadderton there had been great improvement. "One Chadderton manufacturer had thanked her for saving him £12 per week in coal." The rector of St. Stephen's, Salford, spoke of the "enormous quantity of soot for ever falling and finding its way into every part of his house." The deputy mayor (Sir Richard Mottram) and the mayor (Alderman R. Husband) expressed their sympathy with the object of the deputation, but the former mentioned the difficulties of small manufacturers in the matter of boiler expansion, and said that "if smoke prosecutions were pushed too far they would drive manufacturers out of the borough." He did not say that they would so reduce the price of gas as to make it economical to use gas engines or that they would do all they could to favour the use of electricity as a source of power, and yet it is pretty evident that the extended use of gas or electricity promises the best solution at present known of the problem how to carry on manufacturing processes with the least possible pollution of the air. But it is something to have the sympathy instead of the hostility of the corporation in this effort to make Salford in the future brighter and healthier than it is to-day.

THE QUESTION OF THE IDENTITY OF YAWS AND SYPHILIS.

IN 1891, in a preface to Mr. Numa Rat's essay on Yaws, Mr. Jonathan Hutchinson expressed his well-known opinion that the disease was simply syphilis, though modified by race and climate. In THE LANCET of Feb. 13th, 1897, we gave a brief summary of his reasons. Though he has enforced this view repeatedly with his usual dialectic skill and command of facts it does not appear to be accepted by any one who has observed the disease in life. Mr. Hutchinson has of necessity had to take his facts from descriptions and portraits. In the *Indian Medical Gazette* for October Dr. A. Powell presents forcibly the case against Mr. Hutchinson's views. His statements are based on an outbreak of yaws which occurred in Assam. They appear to be the result of careful observation but exemplify the confusion which still exists on the subject. For while the colonial surgeons unite in the conclusion that yaws is not syphilis they contradict one another on fundamental facts. Thus Dr. Powell denies that a primary ulcer ever occurs as stated by Mr. Rat. In the majority of cases a papule first forms which develops into a granuloma, exactly similar to those of the general eruption. Again, he has never seen the tertiary lesions alleged by Mr. Rat, though almost all his cases have remained under observation since 1890. In reply to Mr. Hutchinson's query, "Are there many cases in which it is impossible to decide whether the symptoms are due to syphilis or yaws"? he states that he has never seen such, and that there is no disease—not even small-pox—more definite than yaws. In the secondary stage of yaws in 130 cases he never found the throat affected. But his most powerful argument is the coexistence of yaws and syphilis in the same patient. He observed in two cases of well-marked yaws typical attacks of syphilis—indurated chancres, buboes, symmetrical ulcers of the tonsils, and a macular

Digitized by Google

and roseolar rash. In both the syphilis yielded to mercury whilst the yaws persisted. There are but few cases of this kind recorded. Mr. Hutchinson has admitted that these cases have caused him to suspend his judgment. But as they are so few he asks for corroboration. On the other hand, beyond explaining its infrequency in Europeans from their different habits, Dr. Powell makes no attempt to deal with one of Mr. Hutchinson's most powerful arguments that yaws can be nothing else than syphilis. How is it that such a very contagious malady, of prolonged duration, to which white as well as coloured races are liable, never comes to Europe? On the whole we consider that the weight of evidence is against Mr. Hutchinson's view. But he seems to have established that the diseases are very closely analogous and that yaws may be exactly simulated by a rare form of the secondary eruption of syphilis—the framboesial; also the modified view which he has suggested, that yaws may be the parent stock from which European syphilis has sprung, but that the two, by long transmission in different races, have become modified, deserves attention. But proof or disproof of this seems to be impossible.

OTITIS MEDIA FROM SWALLOWING A PIN.

THE passage of foreign bodies into the Eustachian tube and tympanum is one of the curiosities of medical literature. In his classical work on the ear Politzer cites the two following cases. A patient was chewing oats and a husk stuck in the throat and wandered up the Eustachian tube and through the tympanum to the external meatus. During the use of the nasal douche a piece was broken off the vulcanite syringe which reached the tympanum, caused acute inflammation, and was removed by incision of the membrane. In the *New York Medical Journal* of Oct. 30th, 1897, Dr. Hoover has published the following case. A child swallowed a pin; no symptoms except sore throat followed. After two months she complained of pain in the left ear which was somewhat relieved when a discharge commenced. On examination a small perforation was seen below the handle of the malleus. In using a pledget of cotton-wool it caught in something. A probe was introduced and a small object could be felt. The opening in the membrane was enlarged by incision with a Graefe's knife and again something was felt with the probe which could be moved. With an alligator forceps a small pin about a quarter of an inch long was seized and removed. The child completely recovered in a fortnight.

THE CLINICAL VALUE OF THE WIDAL TEST.

WHEN Ehrlich's diazo test was first introduced as an aid to diagnosis in doubtful cases of typhoid fever it was believed that a most valuable addition to other confirmatory tests for that disease had been secured. Further experience showed, however, that its value was not nearly so great as was predicted. Although doubtless of use in some cases in others the presence of the reaction is misleading and it frequently cannot be obtained until other phenomena, such as the appearance of the eruption, place the diagnosis beyond all doubt. The Widal test seems likely to have a similar history. The earlier reports were all in its favour, but later investigations tend to show that it often cannot be obtained in doubtful cases afterwards proved to be typhoid fever. It is too early yet to come to any positive conclusion, but as all evidence on either side is important we draw attention to a paper on the subject by Dr. W. Gilman Thompson, of New York, in the *Medical News* (New York) for Oct. 30th. His conclusions are drawn from an examination of 503 cases, 157 being undoubted enteric fever. He remarks that the Widal test is unquestionably ingenious and it constitutes a most instructive and suggestive bacteriological demonstration, but he asks, Is it more than this? Is it of genuine, practical, diagnostic value to the clinician? The great majority, fully 75 or 80 per cent. of cases of typhoid fever, need no confirmatory test beyond the plain history and symptoms and the remainder, in which such a test if accurate and exclusive would be invaluable are chiefly (1) cases of enteric fever seen very early in the course of the disease, principally in private practice; (2) cases of obscure sepsis; (3) severe or protracted cases of malarial remittent fever; (4) certain cases of typhus fever and of acute miliary tuberculosis; and (5) various atypical forms of enteric fever. Dr. Thompson might well have added cases of influenza which frequently simulate typhoid fever having an acute onset. With regard to the earliest day of the disease at which the reaction has been distinctly observed it must be admitted that the reaction may be obtained toward the end of the first week, although the reported tests which would confirm an earlier diagnosis are few and uncertain. Dr. Thompson gives a summary of his results thus: 1. While the test is positive in the large majority of cases of enteric fever and negative in the greater number of other diseases there is a margin of error of 11 to 12 per cent. on each side of what might be called the normal line between cases in which the test fails where it ought to succeed and succeeds where it ought to fail in order to make it of real clinical value. 2. This total of 23 per cent. of possible error includes unfortunately just those cases in which there is the greater doubt upon the purely clinical side. 3. As a genuine diagnostic aid the test has about the value of the diazo reaction in typhoid urine or the study of leucocytosis in pneumonia—that is, it is confirmatory in connexion with appropriate symptoms but misleading if positive reliance be placed upon it. 4. The fact that an expert bacteriologist is required to make the test is offset by the ease of transportation of specimens of dried blood which long retain the power of reaction, and it is greatly to be hoped that further possible improvement in technique may place this most ingenious test upon a firmer practical basis than can at present be claimed for it.

CONGRATULATORY DINNER TO SIR WILLIAM GOWERS.

ON Nov. 25th the Society of Medical Phonographers gave a dinner to their distinguished president, Sir William R. Gowers, Sir William H. Broadbent occupying the chair. Among the guests were Mr. Rudyard Kipling, Sir William Thomson (Dublin), Sir Henry Howorth, Professor Bonney, Mr. Reed, the well-known phonographer, and others. The existence of this society is entirely due to the energy and perseverance of its present head, Sir William Gowers, and the members decided to hold a dinner to congratulate him on the recent honour which Her Majesty has been pleased to confer upon him. The honorary secretary, Dr. Neil, presented an illuminated address indicating the indebtedness of the society to Sir William Gowers' fostering care and expressing admiration of his qualities as a distinguished man of science. The chairman in proposing Sir William Gowers' health referred to his published works translated into nearly all European languages as marking an era in the history of diseases of the nervous system. Besides "his own original contributions to our knowledge, he has taken up knowledge wherever it is to be found—he has taken up what we may call the raw material working that out into a piece of beautiful texture." Referring to Sir William Gowers' paper on the Dynamics of Life he characterised it as "one of the most thoughtful, one of the deepest and most interesting, pieces of work" that he had ever perused. In replying, Sir William Gowers gave a short history of his life as a student and pointed out that it was to his knowledge of shorthand he attributed his success in his professional career. Because of

Digitized by Google

his ability to use phonography he was appointed private secretary to Sir William Jenner, which appointment prevented his accepting a partnership in a practice at Bournemouth. This proved to be the turning-point in his life. The toast of the visitors was proposed by Dr. Neil in a felicitous speech and replied to by Mr. Rudyard Kipling, Sir William Thomson, Sir Henry Howorth, Rev. Dr. Jessop, and Mr. Reed. No author has more medical readers than Mr. Kipling. His breeziness, romanticism, and virility are exactly the qualities that commend him to us. It was therefore with great pleasure that we learned from his lips his excellent opinion of "the doctor."

ENGLISH RECOGNITION OF ITALIAN SCIENCE.

OUR Rome Correspondent writes:—"The Cambridge Philosophical Society has just nominated as honorary member an illustrious leader of one among the 'auxiliary forces of medicine,' Signor Augusto Righi, Professor of Electro-physics in the University of Bologna. Professor Righi is in excellent company the Cambridge Philosophical Society having also conferred the same honour on M. Ludwig Boltzmann, Professor of Theoretical Physics in the University of Vienna, and Professor Mendelejev, Professor of Chemistry in the University of St. Petersburg, the distinguished Russian chemist. Hitherto only two Italians have been similarly honoured, the celebrated mathematician, Francesco Brioschi, Director of the Polytechnic Institute at Milan, and Luigi Cremona, Professor of the Higher Mathematics in the University of Rome. Professor Righi has recently made many important studies on the nature of those electro-static waves so brilliantly utilised by the young Italian physicist, Signor Marconi, for his 'telegraphy without wires.'"

AN ACTION FOR MALPRAXIS IN DENTISTRY.

AN action has recently been heard in Manchester in which a man sought to recover damages for malpraxis against an unregistered dental practitioner who, it was alleged, had fractured the jaw of the plaintiff in the process of extracting some teeth and, as a result, much unnecessary pain was caused and a certain amount of necrosis supervened. Evidence on behalf of the plaintiff was given by the plaintiff himself, two medical men, and a properly registered dentist, while for the opposite side the defendant, two medical men, and a member of the Victoria Dental Hospital gave evidence. The plaintiff obtained £50 damages. This case affords another glaring instance of the way in which the public fail to be protected by the Dentists Act from the unregistered practitioner and shows in a forcible manner that more energetic measures should be taken by the Legislature to see that the Act does not become a dead letter. A question of ethics is also raised by this case—namely, the propriety of the giving of evidence on behalf of unregistered practitioners by registered medical men and dentists. This is always a regrettable position for a medical man to find himself in, though we do not forget that such evidence can be compelled by subpœna.

REFRACTION AND GLYCOSURIA.

AT the meeting of the American Ophthalmological Society in May Dr. Risley read notes of two cases of Diabetes in which diminution of the glycosuria was attended with a curious result—loss of refractile power and *vice versâ*. Thus in a man whose urine was of the specific gravity of 1050 the glycosuria and thirst disappeared under nitrate of uranium and his general health improved. But his vision grew rapidly worse and it required an addition of 4 D. to restore it to normal. The glycosuria reappeared and the refraction was again increased so that his glasses had to be reduced by the 4D. Dr. Risley endeavoured to explain these changes of refraction by the theory that the indices of refraction of the media of the eye were affected by the sugar or other elements. In the *New York Medical Journal* of Oct. 2nd Dr. C. Prentice has discussed the question. He rightly points out as an objection to this theory that an opposite result should be expected—a lower state of refraction with a higher specific gravity of the urine and *vice versâ*. He suggests that the low refractive state was induced by a cessation of ciliary innervation (from what cause he does not state), and that with this there was depression of the renal nerve centres to irritation of which the glycosuria was due. He states that for some years he has followed the practice of lowering ciliary innervation by over-correction with stronger convex lenses and prisms than are required for vision in cases of diabetes, and thereby has produced diminution and even disappearance of glycosuria, of thirst, and of polyuria. Dr. Risley's observations bear the stamp of accuracy and deserve investigation. But what shall we say of Dr. Prentice's theory? If glycosuria is ever caused by disturbance of any particular centre it is the hepatic and not the renal. There is no proof whatever that such disturbance is an irritation. But granting so much, we must now make another, and almost incredible assumption—that diminution of the action of the ciliary centre, produced by wearing a pair of spectacles, could so profoundly modify this glycosuria centre as to restore it to its integrity. Finally, in Dr. Risley's cases there was no over-correction of vision to start this wonderful process. But let us not be too severe, for are not other branches of medicine permeated by these nerve-centre explanations which are only assumptions?

ASCARIDES PRODUCING SYMPTOMS OF TYPHOID FEVER.

THE production by round worms of a state resembling typhoid fever has not, as far as we know, been noticed in this country; but in France it has of late years attracted the attention of several writers and its reality cannot be doubted. "Lumbricose à forme typhoïde" is the subject of an article by Dr. A. Chauffard in the *Semaine Médicale* of Nov. 27th, 1895, and more recently of a Thèse de Paris of M. Tauchon. The matter did not escape the observation of the older French writers, for, as Dr. Chauffard points out, his case was typically one of "la fièvre putrido-vermineuse" described in 1770 by Lepecq de la Clôture. The latest contribution to the subject is an article by Dr. Pierre Marie in the *Journal des Praticiens* of Nov. 6th, 1897. In the beginning gastro-intestinal symptoms predominate; there are anorexia, fœtid breath, dyspeptic tongue, attacks of vomiting, and very marked tympanites. To these nervous symptoms are added headache, somnolence, and weakness, which may be followed later by hebetude; sometimes there is vertigo and even convulsions occur. Pyrexia is well marked but does not exceed 104° F. Usually the evening temperature lies between 102·2° and 103·1° and the morning temperature between 100·4° and 102·2°. The spleen is but little or not at all increased in size. Sometimes, as in typhoid fever, epistaxis occurs. On the other hand as points of difference there are no rose spots and no characteristic course of typhoid temperature. Dr. Chauffard's patient was a lad, aged eighteen years, who was admitted to hospital in a miserable condition with drawn features and sunken eyes, dry lips, stupor, and headache. There were general abdominal tenderness, gurgling in the ileo-cæcal region, and slight swelling of the spleen, all pointing to typhoid fever and this disease was in fact diagnosed. But it was noted that the tongue was not characteristic of typhoid fever, being large and flabby and red only at the edges, and that the breath had a strong odour of putrefaction. The temperature ranged up to 102·2° and repeated epistaxis occurred. On the fifth day after admission a

Digitized by Google

round worm was passed, on the eighth and ninth two were passed, and on the tenth one was vomited. Santonica was administered daily in doses of from one to two grammes and worms were passed in numbers—as many as twenty-eight in a week. After this the fever ceased, the patient gained weight, and convalescence was established. But the administration of the anthelmintic was continued and worms were passed though in smaller numbers for several weeks afterwards, in fact, as late as the end of the second month. How was it that the parasites resisted treatment for so long a time? Dr. Chauffard's explanation is as follows. Worms existed in the intestine in different stages of development and only the mature ones were affected by the vermifuge. As proof of this is the fact that they are never expelled except in this stage. Young ones have only been found in the intestine at necropsies. Moreover after each administration of santonica the ova disappeared from the fæces for two or three days and then reappeared.

THE CHOICE OF A TOBACCO-PIPE.

IF tobacco-smoking is justifiable at all on hygienic grounds it is generally conceded that the pipe is the least injurious means. But tobacco-pipes differ considerably in material and shapes, both of which must be important factors in determining the character of the smoke. Thus there is the clay, the meerschaum, and the various wooden pipes, the briar, cherry, or myall. Next to the tobacco therefore, which should always be pure and free from added flavouring, an expedient which is resorted to far too commonly nowadays, probably in many instances to cover an inferior quality of tobacco, the best kind of pipe is a point to be considered. Even assuming that he is smoking good tobacco the smoker knows how different in character the smoke is when drawn from a clay or a wooden bowl. There is probably a scientific explanation of this fact which must have some bearing on the noxious or innocuous character of the smoke associated with other products of combustion. A soft clay is invariably cool smoking because the acrid oils obtained on the destructive distillation of the tobacco are absorbed instead of collecting in a little pool, which must eventually either by the volatilisation or by mechanical conveyance reach the mouth. A particular pipe "smokes hot" not necessarily because the temperature of the smoke is high but because it favours the passage by one of these means of the oils into the mouth. Meerschaum is another porous material. Again, an old wooden pipe or briar, so dear to inveterate smokers, becomes "smooth smoking" because the pores of the wood widen and so absorb, as is the case with clay and meerschaum, a large proportion of the tobacco oils. Thus an old pipe "sweats" as it is termed—that is, the oil intrudes into the expanded pores of the wooden bowl and at length exudes. Similarly, a hook-shaped pipe must be better than a pipe the bowl of which is on the same level as the mouth, for the simple reason that in the former a considerable quantity of the oil is kept back in the U-shaped part of the pipe while in the latter the oil travels easily down the stem. Ebonite stems are in general objectionable because they commonly spoil the true flavour of tobacco smoke. This is most probably due to the sulphur of the ebonite combining with the volatile oils in the smoke. We know instances where ebonite stems have produced distinctly objectionable symptoms in the throat most probably for the reason just given. Bone or real amber makes a much more satisfactory stem or the pipes should be of wood throughout. Amber substitutes, and especially celluloid, should be discarded entirely as dangerous, while the flavour of camphor which these invariably communicate to the smoke forms a very unpleasant combination. Pipes of special construction cannot be regarded with much favour such as those which are said to be hygienic and usually contain a so-called nicotine absorber. Those smokers who require such auxiliary attachments had better not smoke at all. As a matter of fact tobacco yields little nicotine in the smoke produced on its partial combustion; it is mainly to oils of a tarry and acrid character that the toxic symptoms of tobacco-smoking are due.

DEGENERATION OF THE NEURON.

IN the October number of the *Journal of Mental Science* there is a short account of an able and interesting communication made by Dr. Mott at a meeting of the South-Eastern Branch of the Medico-Psychological Association. The neuron, he pointed out, must be considered as a very complex cell with processes, one of which is the neuraxon or axis cylinder process, the others being the dendrons. The neuron consists of two substances, one stainable by basic dyes and the other unstainable by such. If the cell undergoes chemical changes either of hydration or of dehydration regeneration, he thought, was probably impossible. He also pointed out the probability of the production of toxins as a result of degeneration of nervous structures, and he explained many phenomena of general paralysis—e.g., degeneration of heart and other muscles—by such auto-intoxication. General paralysis, he thought, depended upon a primary progressive degeneration of the neuron affecting chiefly the neurons of association, but starting sometimes in the afferent or efferent projection systems and producing respectively the ataxic and lateral sclerosis type. The secondary inflammatory phenomena, he thought, were due to irritation by the products of degeneration, and so in this disease were found congestive stasis, anæmia, epileptiform discharges, &c. Each fresh seizure resulted in an access of degeneration, thus producing a vicious circle and leading to progressive destruction of the whole nervous system. As to the influence of syphilis, in general paralysis as in locomotor ataxy he regarded syphilis as a most potent factor, although the morbid conditions in these diseases were not to be regarded as true syphilitic lesions.

THE WATER-SUPPLY OF COUNTRY DISTRICTS.

IT is surely a most unusual thing for a medical officer of health to be obliged to use terms such as are found in Mr. Parker's annual report to the Lancaster rural council. He says: "It is at least seven years since I first drew the authority's attention to the fact that the water-supply of Cookerham, Thurnham, and Glasson Dock was most unsatisfactory. It is still in the same state or if possible worse. No remedy has been found for this sad state of affairs. No notice has been taken of the matter and it seems almost useless for me to refer to it." The district named is close to the sea and is mostly low-lying. The large majority of farms have no water at all except rain water and that which is got from the dykes. These receive the drainage of the land and in several cases liquid manure from cow-houses. The village of Glasson Dock possesses a few pumps which yield a supply of brackish water, but the bulk of the population drink water from the dock basin. This is connected with the canal which is partly supplied from the River Conder after it has passed through a village named Galgate and received the drainage of several houses. Moreover, the canal is the favourite place for disposing of dogs and no less than twenty of their decomposing bodies have been seen within a distance of little more than 100 yards. A member of the council glories in the statement that he has drunk the water for twenty years without ill effect, which of course proves nothing. The Local Government Board is now moving in the matter and one of its inspectors is attending the meetings of the rural council.

Digitized by Google

The plan that he supports is that the Lancaster water, which is excellent in every way, should be supplied, but the proposal is meeting with considerable opposition. The state of things really seems to be very serious and a heavy load of responsibility rests on the authorities after the facts have been so strongly and persistently placed before them.

THE SALMON CLAUSE AND APPRENTICES' INDENTURES.

IN THE LANCET of Sept. 25th we commented upon some researches of Dr. T. N. Brushfield into this matter which showed that the existence of the clause was very doubtful. A correspondent, however, writes to us enclosing the views of a learned antiquarian from which we extract the following:—"I look upon the statement as correct. There would scarcely be documents to prove it because servants are hired verbally as a general rule. ..... My impression is that it was only in localities where salmon was superabundant ..... and there was no proper market ..... that this stipulation was resorted to." Our correspondent goes on to say that salmon probably followed the price of all other articles of food and that it is money which has fallen in value not salmon which has risen in price. For instance, feuduties or ground rents in Scotland used to be payable either in money or in a good fat hen. In a document dated 1779 the feuduty is fixed at twelve good fat hens or 6*d*. sterling each. A fat hen is now worth 3*s*., but it is the value of the coin which has fallen. Many years ago the means of transport were very imperfect and fish being a perishable commodity would be very cheap. In this way, our correspondent thinks, the stipulation arose and would arise again were the same state of things to come about. Most likely, however, there never was any written agreement to this effect, so that Dr. Brushfield's inability to find an indenture setting forth this clause is thus explained.

ATTACKS OF MIGRAINE WITH ELABORATE VISUAL PHENOMENA.

A VERY interesting and unusual case of severe headache associated with visual hallucination and convulsive attacks is published by Dr. John K Mitchell in a recent number of the *American Journal of Nervous and Mental Diseases*. The patient is a native of the West Indies whose health has been good. His age is not stated. The only neurotic history in his family is of an uncle who committed suicide. Three years before he came under observation he began to suffer from recurrent headache accompanied by a curious visual hallucination. He first becomes aware of the approaching attack by impairment of vision. Then he has a vision of a tiny dwarf appearing at a great distance. This figure gradually approaches, becoming larger and larger, finally assuming the form of a gigantic figure armed with a club. During his approach the headache gradually increases, and when he comes close he seems to strike the patient repeatedly on the head with his club, producing excruciating pain, until consciousness is lost. Violent convulsions usually follow, with arching of the body, so extreme as to cause it to rest on the head and heels. Between the first appearance of the dwarf and the time at which the apparition seems to strike the patient's head as much as eight hours have elapsed. Usually, however, the interval is less. At first the whole attack lasted twenty-four hours, but with more frequent recurrence of the attacks the duration of the individual attacks has lessened. The attacks never occur from December to May. There is a considerable refractive error which has been corrected. There is no history or evidence of malaria and apparently no signs of any gross visceral disease. Dr. Mitchell believes that the condition is really one of severe migraine, for in migraine, he says, it is usual to have (1) slight visual or other sensory disturbance, (2) pain, and (3) nerve storm. In this patient all three phases are present in a marked degree. The periodicity of the attacks also lends likelihood to this view and also the progressively increasing character of the symptoms. Epileptiform convulsions are, as is well known, of occasional occurrence in association with migraine. The case is a very interesting one and suggests the elaborate aurae which have been present in some cases of epilepsy. But the attacks are much more of the character of so-called hysteroid attacks, such as may occur in neurotic patients from any violent nervous disturbance. It will be interesting to know the result of treatment adopted on the supposition that the case is one of migraine.

HEREDITARY SPASTIC PARAPLEGIA.

IN the November number of the *American Journal of Nervous and Mental Diseases* Dr. Weston Bayley gives an account of several members of a family whom he has had under observation. The history of the affection shows that members of the family in five successive generations have been affected with the disease, which is characterised by a spastic condition, coming on as a rule about the fifth or sixth year of life, associated with exaggeration of knee-jerks and usually also ankle clonus, and without any sensory impairments or pupil affection. Dr. Bayley has himself examined nine patients in the family, involving three generations and, as he remarks, it is obvious that they are examples of an hereditary affection of the spinal cord. Of course, instances of family spastic paralysis have been described by more than one observer but Dr. Bayley is to be congratulated on the conclusive proof of its existence which he brings forward by showing its certain presence in three generations of the same family and its all but certain existence in two others.

A FORM OF MULTIPLE NEURITIS IN THE WEST INDIES.

IN the November number of the *Practitioner* Mr. Strachan, of Jamaica, contributes an article dealing with this subject, one to which he directed attention nine years ago in *Sajous' Annual*. A patient suffering from the disease in a typical form presents himself complaining of numbness and cramps in hands and feet, dimness of vision, and tightness round the waist. There is also a burning sensation in the soles of the feet and in the palms of the hands, worse at night usually than in the day, and there is as a rule slight excoriation with fine desquamation at the edges of the eyelids and at the margins of the lips and nostrils. The main nerve trunks in the limbs are tender to pressure and this is particularly true of the ulnar nerve, and along the distribution of the terminal filaments are fine herpetic vesicles. The muscles of the limbs waste and the trunk muscles may become involved and lead to respiratory difficulty. The pupillary reaction is not impaired although vision is much reduced. The external ocular muscles may become affected but this is rarely the case and a fatal termination is uncommon. When it does occur it is preceded by dyspnœa and riotous action of the heart. The mental condition is unimpaired except in the extreme cases in which delusions may be present. The reflexes do not differ in their condition from the condition of these phenomena found in other kinds of neuritis. In the few necropsies which Mr. Strachan has seen the most noteworthy feature was pigmentation of the brain, spinal cord, and larger nerve trunks. The changes in the liver and spleen were such as are usually found in cases of malarial poisoning. There is no mention of any microscopic examination of the nervous system or of the blood but Mr. Strachan is of opinion that malaria is the most probable toxic agent although he also

Digitized by Google

recognises the possibility that the poison may be the result of some micro-organism or other agency at present unknown.

THE Council of the Metropolitan Hospital Sunday Fund will recommend the constituents, who are to be convened on Monday, Dec. 13th, that June 12th be fixed for Hospital Sunday of 1898. We understand that Sir G. Faudel-Phillips, (the late Lord Mayor), Mr. Augustus Thorne, and Mr. Peter Reid will be recommended by the Council to fill vacancies on the Council. The report of the Council for the past year will be published next week.

THE subject of the Hughlings Jackson Lecture to be delivered before the Neurological Society of London by Dr. Hughlings Jackson at 11, Chandos-street, W., on Wednesday, Dec. 8th, 1897, at 8.45 P.M., will be "Remarks on the Relations of Different Divisions of the Central Nervous System to one another and to Parts of the Body."

THE monthly meeting of the South-West London Medical Society will be held at Stanley's Restaurant, 235, Lavender-hill, on Dec. 8th, at 8.30 P.M., when Mr. Victor Horsley will read a paper entitled "The Medical Acts of Parliament; What They Are and What They Ought to Be."

A CONFERENCE of the delegates of the various institutions affected by the scheme of Lord Cowper's Commission will be held at the University of London on Dec. 14th at the invitation of the Senate of the University.

Pharmacology and Therapeutics.

CREOSOTAL.

DR. NORDT has published full details of the very favourable results obtained by Professor von Leyden, of Berlin, in the treatment of phthisis by creosotal. The medicine was given in gradually increasing doses commencing with five drops three times a day and three drops being added daily until the quantity of twenty-five drops three times a day was reached. This dose was continued for a period varying from one to four weeks, after which the quantity was reduced and increased again. The night-sweats and fever of phthisis obviously became less under creosotal, while from week to week the bronchial secretion and cough were perceptibly diminished and the physical symptoms of phthisis disappeared completely in two cases in which the treatment had been continued for eight months and ten months respectively. Creosotal is perfectly free from the disadvantage of creosote, no unfavourable effects on the stomach or intestines having been observed in any case.

TETANUS ANTITOXIN.

Dr. Max Engelmann, of Leipzig, having successfully treated three cases of tetanus—two with Tizzoni's serum and one with Behring's—gives a detailed account of the cases in the *Münchener Medicinische Woohenschrift* (No. 32), and adds some remarks concerning the use of these serums in a number of cases published by others. Thirty-four were treated by means of Tizzoni's serum. Only eight terminated fatally and in three of these there were septic complications, four others were given doses that were probably inefficient, and the eighth case came under treatment only a few hours' before death. As no ill effects were produced by the serum he advises that it should be tried in all cases and that where a case appears to be a serious one a large dose should be at once administered. Of course sedative drugs should also be prescribed and the wound if it can be discovered treated on surgical principles. Seventeen cases were treated by means of Behring's serum, with a mortality of seven. In six of the fatal cases and in some of the successful ones the old preparation was used, while others were given the newer dry form. This last is more powerful, and even in large doses does not produce any unpleasant effects. Dr. Max Engelmann has not been able to discover any appreciable difference in the behaviour of the Tizzoni and Behring preparations.

HYPODERMIC INJECTIONS OF COCAINE IN THE VOMITING OF PREGNANCY.

In five cases of the vomiting of pregnancy where morphia injections and cocaine given by the mouth had failed Professor Tibone of the Turin obstetric clinic was able to effect an immediate cure by means of hypodermic injections of hydrochlorate of cocaine. One-seventh of a grain was thus administered just before food was taken, the puncture being made in the epigastrium and the injection repeated two or three times a day. It was found that this enabled the patients to retain their meals, and under this treatment they increased in weight and their condition improved in a marked degree, no unpleasant effect on the pulse, the respiration, or the temperature being observed in any of the cases. As soon as possible of course the cocaine was stopped and the vomiting did not show any tendency to return. Dr. Pozzi who writes on these cases suggests that it is probable that similar treatment may be found valuable in vomiting due to other causes.

The Lancet Special Commission

ON THE

METROPOLITAN WATER-SUPPLY.

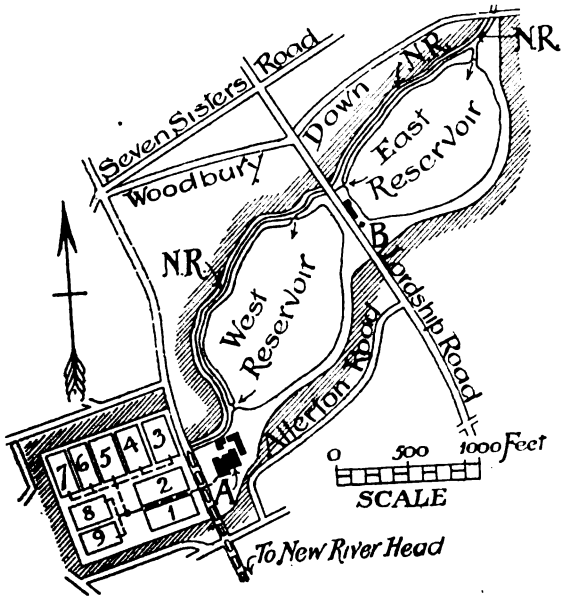
XXI.[1]

NEW RIVER COMPANY.

THE WELLS, PUMPING-STATIONS, AND RESERVOIRS—*Continued.*

IN the previous article the stations of the company between Broad Mead Well (see C in the general map of the Company's works which appeared in THE LANCET of Oct. 23rd, p. 1069) and the Crouch-hill Reservoirs have been described. Continuing the survey towards the metropolis we come now to—

Stoke Newington reservoirs, filter beds, and pumping station (see V on general Map and Fig. 2).—The station at Stoke Newington is situated at Green Lanes. It occupies a large area and is divided into two by the road called Green Lanes. The part to the east of the road consists of two large open reservoirs and a pumping station; the filter beds are situated to the west of the road. The New River enters the eastern reservoir at its north-eastern extremity at Woodbury Down. Almost the whole of the water goes through this reservoir in the direction shown by the small arrows in the diagram (Fig. 2). A small amount of water only passes down the course of the river which is situated just to the north of the reservoir at the bottom of the gardens of the houses on Woodbury Down. The sluice at the part of the river near the inlet into the reservoir is kept almost shut, and through that part of the river which is situated just to the north of the reservoir a sufficient amount of water is allowed to pass so that a gentle flow may keep it sweet by circulation. The eastern reservoir is of somewhat irregular oval form, and covers an area of about 21½ acres and has an average depth of about 16 ft. except near the banks. It is surrounded by a puddle wall which goes down to the London clay. There is a grass walk all round and the eastern and southern sides are protected from the wind by a luxuriant thorn hedge. The available capacity of the reservoir is confined to the upper 3 ft. At the western side of the reservoir there is a disused engine house now occupied as a store; the engine was formerly used for pumping to the reservoir at Claremont-square but it has not been used for many years. From the eastern reservoir the water passes into the New River and in a south-westerly direction under Lordship-road, and then into the western reservoir. The area of this is about the same as that of the one just described and it is constructed on the same principle, that



[1] Nos. I., II., III., IV., V., VI., VII., VIII., IX., X., XI., XII., XIII., XIV., XV., XVI., XVII., XVIII., XIX., and XX. were published in THE LANCET of Feb 20th and 27th, March 6th, 13th, 20th, and 27th, April 3rd, 17th, and 24th. May 1st, 8th, 15th, 22nd, and 29th, June 19th and 26th, Oct. 23rd, and Nov. 6th, 13th, and 27th respectively.

Digitized by Google

is to say, it is surrounded by a puddle wall and the bank-slope down gradually. The reservoirs together have an available capacity of about 90,000,000 of gallons, and roughly speaking the water remains in them for from two and a half to three days.

Filter beds.—There are nine filter beds which have a total area of about 8½ acres. On June 14th two of these were not in use; the one marked 3 was being cleaned and the one marked 5 was being re-sanded. Nos. 1, 2, 3, 4, and 5 are constructed on the same plan. The upper part of each is lined with blue Staffordshire bricks. The sides, which are lined with bricks and concrete, slope as 2½ to 1. The composition of the filtering material is as follows:—sand 2 ft., shingle 3 ft. For the collection of filtered water there are two culverts. To these culverts drain pipes, 10 in. in diameter, conduct the filtered water. These lateral pipes are arranged in lines which are at a distance of about 8 ft. apart, and the pipes run into the culverts. The upper part of the culvert is flat and is covered with flagstones. Each

FIG. 2.

Stoke Newington Station. N R, New River. A, Engine house. B, Disused pumping station. 1, 2, 3, 4, 5, 6, 7, 8, 9, Filter beds.

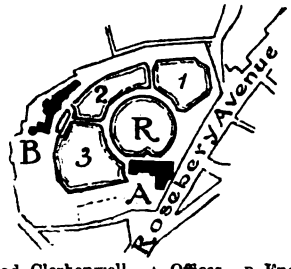
culvert has an air-shaft which has its outlet at the end of the bed. Filters 6, 7, 8, and 9 were built after the others, and they differ slightly in construction. The sides of these beds are nearly vertical. The filtering material consists of 2 ft. of sand and 6 in. of fine shingle (here called "pea shingle"). The method of collecting the filtered water in these beds differs from that adopted in those just described. In the newer beds the channels for the collection of the filtered water were formed of two courses of bricks built to form channels; no mortar was used. Each of these beds has one air-shaft, the outlet of which opens at the side of the bed. The other extremity of the shaft passes down to the bottom of the bed.

Cleaning filter beds.—As a rule a bed is used for about six weeks. It is cleaned by removing about a quarter of an inch of sand from the surface. The sand is washed in a place specially built for the purpose, which consists essentially of a number of bays formed of concrete. The sand is first placed on a hopper and subjected to jets of water at a pressure of 150 ft. head. From the hopper the sand passes through troughs into the washing bays, where it is cleaned by water which plays on it from a hose at a pressure of 150 ft. The amount of water used in washing the sand is about 3000 gallons per cubic yard.

Rate of filtration.—The rate of filtration is from 2½ to 4 gallons per square foot per hour.

Gauge.—There is a simple instrument in use at this station for gauging the rapidity of the filtration. It consists essentially of a diaphragm which is placed in the stream of water which flows from the filtered water culvert to the engine wells. The current of water acting on the diaphragm moves a lever to which an index is attached, and the index is thus able to show on a graduated gauge the rate at which the filtered water is passing out, the gauge being so graduated that it records the result in terms of gallons per square foot per hour. The arrangement is a simple one and is certainly worthy of general adoption. The filtered water passes into a shaft 16 ft. in diameter, from which it is conducted into a culvert as far as the boundary of the western part of the Company's property; it is then conducted under the road (Green Lanes) in two 48-in. pipes to the engine well.

Pumping arrangements.—There is a compound engine having cylinders 48 in. and 77 in. in diameter respectively and a stroke of 8 ft. This is worked at a pressure of 70 lb. and pumps the water to Crouch Hill reservoir against a head of 100 ft. As a rule this engine is worked for about eleven hours a day, and the water supplies Hornsey, Stoke Newington, Edmonton, and part of the City.



There are two pairs of compound engines, Nos. 3, 4, 5 and 6. Of these Nos. 3 and 5 are compound beam-engines with steam drop valves arranged with a high pressure cylinder mounted on a base in front of the low pressure cylinder. The diameter of the high pressure cylinder is 28 in., that of the low pressure cylinder is 46 in., and the strokes are 5 ft. 6⅜ in. and 8 ft. respectively. Nos. 4 and 5 are compound beam engines with steam slope valves. The diameter of the high pressure cylinders is 22 in. and that of the low pressure cylinders 36 in. The strokes are 5 ft. 6 in. and 8 ft. respectively. Of these engines Nos. 3 and 4 are worked together being coupled on one fly-wheel 24 ft. in diameter. Engines 5 and 6 are also coupled on a fly-wheel.

Another house contains a compound Worthington engine with high duty attachments. Of this engine the cylinders are 27 in. and 54 in. in diameter respectively, and the stroke is 3 ft. 6 in. This engine is capable of pumping 9,500,000 gallons of water daily and is used for pumping water to Maiden-lane, working against a head of 150 ft. The Maiden-lane reservoir supplies the higher district.

Amount of water pumped.—On June 14th water was coming down the New River to Newington at the rate of 31,000,000 gallons in the twenty-four hours. Of this quantity 25,000,000 gallons were filtered at Stoke Newington, and pumped to Maiden-lane, to Crouch Hill, and to the districts between Stoke Newington and those places. The other 6,000,000 gallons of water passed on down the New River to New River Head, Clerkenwell.

Workshops.—This station contains a large workshop and also cottages for caretakers.

FIG. 3.

New River Head, Clerkenwell. A, Offices. B, Engine house and workshop. R, Reservoir. 1, 2, 3, Filter beds.

New River Head, Clerkenwell (see W on Map and Fig. 3). The area of the station at New River Head is about eight acres. It is surrounded by a high brick wall. The house formerly occupied by Sir Hugh Myddelton, first governor of the Company, was situated here and part of it is now occupied by the offices of the Company. (Fig. 3, A). In addition to these, the station contains a small open subsiding reservoir, filter beds, pumping engines, a yard containing stores, and a large workshop. The water from the New River is received into a subsiding reservoir (Fig. 3, R), which has an area of about an acre, and is capable of holding 700,000 gallons. It is of circular form and lined throughout with stone. The flow of water into it is regulated by a cock. The water has very little time to remain in this reservoir, for the amount pumped daily from the station is about 6,000,000 gallons, therefore the water in the reservoir is changed several times daily.

Filter beds (Fig. 3; 1, 2, and 3).—There are three filter beds which have a total area of about two and a quarter acres. They are of somewhat irregular shape, as may be seen in the accompanying plan, which was taken from the ordnance

Digitized by Google

map. The sides of the filter beds are nearly vertical, and are lined with stone. The composition of the beds is as follows: Sand 2 ft., shingle and stones about 5 ft. The stones vary in size from that of a bean upwards. The smaller ones are placed at the top and larger ones below. Each filter bed has two culverts for the collection of filtered water. The culverts are square in form at the bottom and are built of brick. The water at the bottom of the bed is collected into a central culvert by U-shaped pipes, which are laid in lines at a distance of about 10 ft. apart. The diameter of these pipes is 6 in. The end of each filtered water channel is ventilated by a 4-in. iron pipe. This ventilating pipe is situated at a distance of about 4 ft. from the edge of the filter bed. The three filter beds are all constructed on the same plan and differ only in shape. Near the filter bed No. 1 there is a place for sand washing and a similar one is situated near bed No. 2.

Cleansing sand.—The arrangements for sand washing are similar to those at the other stations of the Company. Near the larger filter bed there are three bays for sand washing. The pressure of water is 120 ft. and the amount of water which is used for washing a cubic yard of sand is 3000 gallons.

Pumping arrangements (Fig. 3, B).—There are two engine houses called respectively east and west. The engine in the eastern house is in course of removal. The western house contains a beam engine made by Boulton and Watt in the year 1810. The steam cylinder is 44 in. in diameter, and the stroke is 8 ft. There are two pumps having barrels of 29 in. and 18 in. respectively, and strokes of 8 ft. and 6 ft. The steam is generated by two Lancashire boilers, and both the engines work at a pressure of 20 lb. It may be of interest to note that when the engines were first put up the steam was generated by copper boilers and the pressure used was only 4 lb. The water was formerly pumped through a stand-pipe; at the present time a large air vessel is used instead. The water is pumped to the High Pond reservoir, Claremont-square, a lift of 50 ft. The new engine which will be put up is an over-head three-cylinder engine of marine type capable of working at a pressure of 120 lb.

Workshop.—There is a large workshop in which taps and ball valves are tested and those found to be efficient are stamped with the Company's mark. An enormous amount of this work is now done, the number of taps tested being sometimes not less than 50,000 a week. Taps are tested to stand a pressure of 300 lb., which is about equal to a column of 670 ft. of water, which it may be noted is a much heavier pressure than they would be likely to sustain in actual practice.

High Pond reservoir, Claremont-square (see X on Map).—This reservoir is situated in the centre of Claremont-square, Clerkenwell. It is on the site of a high service pond which was formerly used. The present reservoir is covered with brick arches supported by brick piers. The sides are nearly vertical, the slope being 1 in 12. The bottom of the reservoir is lined with York paving stones set in cement. There are 30 cast iron ventilators and 8 circular manholes 5 ft. each in diameter. These are covered with galvanised iron sheeting. The reservoir has a capacity of 3,500,000 gallons; the top water level is 139 ft. above ordnance datum. Here there is a standpipe 45 ft. in height. There is a clock-work recording gauge here and a tabular gauge at the pumping-station at New River Head, whence the reservoir is supplied. The water is used for high service supply to the city. The reservoir is surrounded by a cast iron spiked railing.

Hampstead reservoir (see Z on Map).—There is a covered reservoir at the highest part of Hampstead Heath near the flagstaff. It is triangular in form, built of brick set in cement. It is covered by brick arches which rest on iron joists, which are carried by iron pillars. The reservoir is ventilated by iron shafts. It is surrounded by an iron fence and is covered by turf. Water is pumped here from Hornsey-lane and is used for the supply of the highest districts of Hampstead. There is here a stand-pipe 40 ft. in height, the top of which is 486 ft. above ordnance datum, and which is used for the supply of the highest services in the immediate vicinity.

Highgate reservoir (see AA on Map).—The reservoir at Highgate is situated near South-grove on the highest part of Highgate Hill. The area occupied is about two acres. The capacity of the reservoir is 1,000,000 gallons. The sides of the reservoir are built of brick set in cement, and the slope is 1 in 2. The depth in the centre is 12 ft. The reservoir is covered with a slate roof supported on iron joists. The water is pumped here from Hornsey-lane and is distributed to the higher parts of Highgate. There is a stand-pipe 6 in. in diameter and 50 ft. in height, the top of which is 481·8 ft. above ordnance datum. It is used for the high service of houses in the immediate neighbourhood. There is a small round-house which contains a cockpit and is used also for keeping tools. An iron railing surrounds the reservoir.

Hornsey-lane reservoir and pumping station (see BB on Map).—Water is pumped to this station from Hornsey, and is pumped hence to Highgate and to Hampstead.

Pumping arrangements.—There is a compound beam engine which has a high pressure cylinder 17 in. in diameter, and a low pressure cylinder 29 in. in diameter. It works two pumps which have cylinders 18 in. in diameter and a stroke of 2 ft. 6 in. The rate at which the pumps are worked is from 27 to 28 per minute. The steam for the engines is generated by two Galloway boilers, one only of which was working when visited. The steam pressure is 80. The head of water worked against in pumping to Highgate is 103 ft. and to Hampstead 133 ft. For six hours a day water is pumped against a head of 150 ft. over the stand-pipes at Hampstead and Highgate for the supply of the highest parts of those districts.

Another engine house contains a simple low pressure horizontal engine which works a double action pump which has a barrel of 12½ in. in diameter. The length of the stroke is 6 ft. and the engine works at a rate of twenty-two strokes a minute. This machine is not generally used, the engines first described having sufficient power to do all the pumping usually required by working for twelve hours or so daily.

This station is in telegraphic communication with Green Lanes, but not with the reservoirs at Hampstead and Highgate, so that when it is necessary to communicate with these stations a messenger is sent.

The reservoir is situated close to the engine house on the west side of Tile Kiln-lane next to Hornsey-lane. It is covered with brick arches which are turfed over at the top; the slope of the sides is about 1 in 6. The reservoir is ventilated by 6-in. cast iron pipes, it has a capacity of 3,000,000 gallons and the top water level is 348·2 ft. above ordnance datum. The reservoir occupies from two and a half to three acres and is protected by a high wall.

Maiden-lane reservoirs (see CC on Map).—This station is situated on Dartmouth Park Hill, Camden Town. There are two covered reservoirs and a cottage occupied by a street foreman—a man in charge of the arrangements for the local distribution of the water. The total area occupied is about ten acres. The reservoirs are capable of holding 15,000,000 gallons of water. The top water level is 232 ft. above ordnance datum. The reservoirs are covered with brick arches which are turfed over at the top. Each is ventilated by sixty cast iron ventilators, and there are ten inspection- or man-holes, which are covered with galvanised iron. There is a large cock-pit adjoining the reservoirs. This is covered by brick arches. It is 30 ft. in length and 20 ft. in width. Through it pass two 36-in. pipes which convey the water into the reservoirs and there is also a 24-in. overflow pipe which goes into the sewers. This pipe is provided with cocks which can be open or shut from the cock-pit. The pipes are 30 ft. below the surface of the ground. The pit is used for emptying the reservoirs when necessary, and when this is done the water passes first into it and then into the sewers. It has three divisions: (1) a central one into which the water passes before it is discharged into the sewers when the cistern is emptied for cleansing purposes; (2) the second division has a 36-in. supply and delivery pipe for the southern reservoir; and (3) the third division has a 36-in supply pipe for the northern reservoir. The water is pumped here from the Green Lanes station and is used for the supply of the district.

Gauge house.—At the south-east corner of the reservoir there is a gauge house. It is fitted up with a battery which records at the Green Lanes pumping station the amount of water in the reservoir. The electric arrangements are managed by the General Post Office. The construction of the gauge is briefly as follows: there is a copper float which is connected with a balance weight by a copper wire which runs on grooved wheels so arranged that each alteration of one inch in the water level is recorded.

DISUSED STATIONS.

A brief description may here be given of the disused stations at Cheshunt and Tottenham.

Cheshunt.—The station at Cheshunt is situated on the

Digitized by Google

right side or lower bank of the New River. There are two large reservoirs here and a well. The only use which is now made of this station is that there is a smithy here. The well has not been used for years. It was found that the level of the water in it was affected by the pumping at the station at Turnford, which is about three-quarters of a mile off. This well has, in fact, been disused since the new well has been sunk at Turnford. It is estimated that 750,000 gallons of water could be obtained daily at Cheshunt. The old machinery which is situated here consists of a single cylinder beam engine with gear working bell cranks. There are two large reservoirs. When these were made the idea was to store water in them, obtaining some, if necessary, from the New River and some from the well. The water which comes into these reservoirs at the present time is derived from the surface drainage of the country around. This water is not now, and has not been for many years, used by the New River Company as a source of supply. The surplus water from the reservoirs passes under the New River in a conduit made for that purpose and passes down into the River Lee.

Tottenham.—There is a disused pumping station in Ferry-lane, Tottenham. It was formerly used for pumping water from the River Lee into the New River at a point near the Seven Sisters-road. This, however, has not been done for more than thirty years.

Pumping arrangements.—There is a Cornish pumping engine which was worked by steam generated by three Cornish boilers. The engines are bright and clean; the boiler fittings have been removed. A workshop and caretaker's cottage are situated here. Near the pumping station there were formerly two mills which belonged to the New River Company. The water was taken from the mill tail and the New River Company had a sluice which was regulated so as to supply the mill tail with water as it was required without the necessity of its passing through the mill race. One of the mills was burnt down many years ago and the other has been dismantled. The water was formerly taken from the mill tail through cast iron gratings with ½ in. spaces and ½ in. bars; these remain *in situ*.

(*To be continued.*)

LEICESTER AND SMALL-POX.

(*Continued from p. 1408.*)

RETURNING now to Mr. Biggs we desire to note that with regard to the vaccinated condition of the tramp first attacked in the outbreak there is a discrepancy in Dr. Coupland's report. At page 26 the tramp is described as having "a smooth, small cicatrix" as quoted by us in THE LANCET of Nov. 20th. In the table of cases however (p. 12) under the heading of "Vaccination data" the entry is "Infancy: small smooth marks." Whether the plural or the singular is correct we know not, but in fairness to Mr. Biggs it is right to assume the plural. What therefore remains as regards this particular case is that the evidence being that the tramp, aged thirty-five years, had been vaccinated in infancy, Mr. Biggs declares in 1893 that the tramp "was well vaccinated" though he had previously held that after even nineteen years' interval vaccinal protection "has theoretically expired." His versatility in this connexion is further illustrated by a criticism which he made in the London *Echo* and the *Leicester Post* of Dr. Priestley's annual report for 1893. With regard to the protective power of vaccination against attack by small-pox Mr. Biggs then stated that the Local Government Board had "issued a memorandum fixing the limit at about ten years." This needless to say is simply incorrect. The Board never issued any such memorandum. Mr. Biggs of course has in mind here the Board's opinion that as a precautionary measure re-vaccination should be performed after ten years of age where primary vaccination has been done in infancy. But no one would accuse an insurance agent of declaring a man's stock of vitality to be entirely exhausted merely because of the agent's advice that the man should take out another life policy. On this assertion, however, that the Board had "fixed the limit at about ten years" Mr. Biggs proceeded to declare that of 184,000 inhabitants of Leicester only 10,000 could be looked on as theoretically protected by vaccination against small-pox. This was the same Mr. Biggs who wrote to the *Star* that the Leicester nurses who were attacked by small-pox were well vaccinated, their vaccination having been done in infancy and their ages ranging from twenty to forty-five years.

In Leicester a great deal is made of the assertion that every outbreak of small-pox has owed its origin to an "importation" and it is alleged by Mr. Biggs that such importations have been usually from well-vaccinated towns or districts (Q. 16,205). His Diagram D appended to his evidence before the Commission gives a table of so-called "importations." In 1877 it is admitted that the origin of the disease was unknown and the total number of persons infected was 12. Yet the outbreak is assumed to be due to an "importation." So also in 1885 there is no knowledge of how the disease arose, but the "importation" theory is adopted as a matter of course. It is obvious, indeed, that even Dr. Johnston, the medical officer of health, used the term "importation" very loosely, sometimes as meaning no more than that he could not trace the origin of the disease, as in 1883, when he says: "On the 31st August two additional cases having as far as could be ascertained no connexion with the previous one were reported in Argyle-street, making the fourth and last importation." Most importations are alleged to be by tramps. The "tramp" theory, indeed, is dragged in quite unjustifiably sometimes, as in 1881, when a father and daughter resident in Leicester and attacked in March are counted as a tramp or tramps in Mr. Biggs's table, whereas the first "tramp" visitation of the year is not recorded until May. However, the capacity of vagrants to convey small-pox is very well known and Leicester, like other places in the kingdom, has experienced this. These people travel about all over the country and as most places in this country can still be described as well vaccinated so far as primary vaccination is concerned it is not surprising that various tramps who came to Leicester had previously been in places where vaccination had not been neglected as in Leicester. Looking to the fact that every new appearance of the disease, whether recorded or unrecorded as to source, is described as an "importation," all that can be meant or ought to be meant would appear to be that Mr. Biggs, or whoever was originally responsible for applying the term "importation," did not believe in the *de novo* origin of small-pox, but that when the disease arose in Leicester it came from somewhere and not from nowhere. The same could be equally assumed of every outbreak of small-pox from the days of Rhazes onwards.

With regard to these importations Mr. Biggs, under examination, gave replies which amounted to a confession that evidence given by the chairman of the Sanitary Committee was very far from according with the facts. That witness had declared repeatedly that under the Leicester system all the cases of small-pox which occurred had been imported (Q. 13,238 and 13,240). From Mr. Biggs, on the other hand, Lord Herschell elicited the fact that many of the cases were not imported, but in spite of the Leicester system resulted from imported cases or cases which Mr. Biggs assumed to have been imported, their origin being unknown. Thus, according to Mr. Biggs, of 116 cases in the period 1874–89 only 33 had been imported, even allowing him to attach his own meaning to the term importation. Undeniable as his Table D shows this fact to be Mr. Biggs is exceedingly loth to give it due recognition. Having mentioned that "an epidemic threatened us in 1888 through the importations of small-pox from well-vaccinated Sheffield" (Q. 16,793) it was pointed out to him that he had shown only 2 cases imported from Sheffield in that year. It happened however that from these and other 3 "importations" from other places 16 persons had been infected, making 21 for the year, and that in the latter part of the previous year 2 "importations" (1 from Sheffield) had been followed by 8 cases, making 10 for that year. Adding these together he says (Q. 16 805): "There were 10 cases at the latter end of 1887 and 21 at the beginning of 1888, making a total of thirty-one centres of infection." Thus the Leicester method had failed to prevent the infection of 24 persons from 7 "importations," and straightway the whole 31 are described as "centres of infection" and the method gains new laurels in being able to deal with so great a number. So also Mr. Picton argued in cross-examination of Dr. J. H. Neale, of the Leicester Infirmary. That witness had said to Professor Michael Foster, in reply to a question as to the value of isolation as

Digitized by Google

practised in Leicester, that there had been very little small-pox to test it by, but that if an epidemic of small-pox came similar to an epidemic of scarlet fever which had attacked Leicester, so that there had been many cases waiting for admission to hospital and no beds to receive them, then "the effect might be rather disastrous" (Q. 14 897). Mr. Picton called the witness's attention to this answer and asked him if he was not aware that in 1888 no less than 23 cases of small-pox had been admitted to the hospital, and "as a medical man do not you think it a noteworthy fact that there have been these introductions of the disease into Leicester without any spread of it?" But as a matter of fact the 23 cases themselves included a "spread," for even Mr. Biggs alleges only 5 "importations" for that year. Yet Mr. Picton speaks of the whole 23 as "introductions of the disease into Leicester." In the course of the 70 weeks dealt with in Dr. Coupland's report there were 357 cases of small-pox in Leicester. Taking these as constituting the outbreak, if each of them is to be regarded as an "introduction of the disease," then, no more cases occurring, we reach the conclusion that, shall we say owing to the Leicester method, 357 introductions of small-pox were stamped out without infecting a single individual in Leicester. In the same way if we take say 1500 as the number of cases constituting the epidemic of 1870–73 in Leicester, and call each case a centre of infection or an "introduction of the disease," we find that under a system of primary vaccination even without re-vaccination 1500 centres of infection were "stamped out" without infecting anybody in Leicester, so that the triumph of infantile vaccination was much greater than that of the later Leicester procedure. The kind of argument here adopted by Mr. Biggs and Mr. Picton is so ridiculous that we are almost ashamed to spend time in its refutation.

We may note in passing that Mr. Biggs's statement regarding the quarantined that "compensation for loss of time is *not* offered" is based on a letter which he quotes from the town clerk and which seems definite enough. It is, however, contradicted by information given to Dr. Coupland by Dr. Johnston, the reputed author of the Leicester method. "It was the custom, Dr. Johnston informed me, for the corporation to pay the wages of the quarantined during their fortnight's detention." Between Dr. Johnston and the town clerk we do not pretend to judge, especially as the difference of statement refers to a time when there was very little small-pox in Leicester. When small-pox did come, however, in 1892–93 Dr. Coupland's report shows that payments *were* made for wages and he gives excerpts from the minutes of the Health Committee which leave no doubt about the matter. The Leicester system in the absence of small-pox was one thing. In presence of small-pox it was something else.

Questions relating to the hospital and quarantine have next to be looked at. It was part of the method to carry out quarantine in the hospital and we have seen how loth, according to Mr. Biggs, the quarantined people were to leave their quarters after their time of isolation had passed. "Many," he declared, "had been reluctant to leave the hospital." Turning to Dr. Coupland for a description of the place it hardly appears to have been a paradise. In 1881 Dr. (now Sir Richard) Thorne described the buildings as they were then. They were constructed of wood and galvanised iron. The erysipelas pavilion (where quarantine for small-pox was carried out) was somewhat dilapidated. Both it and the small-pox pavilion had been originally coated with tar but were afterwards whitewashed and remained "very unattractive in appearance." In 1885 the late Dr. Tomkins, then the medical officer of health, told the town council that the hospital was "an ugly makeshift" which had been "constructed hurriedly and on an ill-designed plan" and that it provided "unsatisfactory accommodation for the treatment of small numbers of patients or for the convenient separation of such cases as it may be desirable to isolate from others. It is also in many respects deficient in the accommodation and arrangements adopted in modern hospitals of this description."

This was the charming residence from which the quarantined people of Leicester could hardly be torn away. It was here, too, that the triumphs of Leicester were accomplished as regards both small-pox and other infectious diseases. In 1892-93 Dr. Coupland's comments agree with those of Sir Richard Thorne and Dr. Tomkins. "The sanitary accommodation is bad and I am informed that the building is infested with rats. I cannot avoid expressing the opinion that these two wooden buildings are a reproach to the authorities." Such was the place round which centred the Leicester system. Looking to the decade of boasting of which the system had been the subject it is really surprising that in face of criticism both by the Local Government Board and by its own health officer Leicester did not in defence of its own consistency provide itself with a building which would be something better than an "old shed." "It is not surprising," says Dr. Coupland, "that in 1893 it was found necessary to abandon the system of interning families in the hospital quarters and to substitute for it the practice (which had always been adopted when persons refused to go to hospital quarantine) of daily inspection of infected houses, a practice which is customarily carried out in other towns during epidemics of small-pox." Hospital quarantine, therefore, which, when small-pox was not prevalent, had been described as part of the Leicester method, had to be given up when the outbreak did come. Here also, as with regard to non-payment of wages of quarantined persons, the method was one thing in the absence of small-pox and another thing in the prevalence of small-pox. In short, the Leicester system was triumphant so long as there was nothing to triumph over. It was an excellent, even a "perfected," method when there was no small-pox, but when small-pox prevailed Leicester had to fall back on "a practice which is customarily carried out in other towns." Notwithstanding the assertion of Mr. Biggs regarding non-payment of wages to quarantined persons Dr. Priestley, who was medical officer of health then, stated at the annual meeting of the British Medical Association in 1894 that the cost of hospital quarantine in the outbreak was 25*s.* per head per week for adults and 12*s* 6*d.* for children. The total number of persons kept under observation was 1261. If half of these were children their hospital quarantine would have cost nearly £1200 for a single week. But as we have said small-pox being prevalent the system was dropped.

"We find small-pox very easy to deal with," said Mr. Biggs in 1891,[1] "and the same hospital and staff of officials deal with small-pox as with other infectious diseases."

In 1885 Dr. Tomkins had reported to the town council that the hospital was only an ugly makeshift and that there was not proper accommodation for the separation of different diseases. That, however, was the opinion of a mere medical man, and one who, moreover, though a Leicester official, was actually a believer in vaccination and had the temerity to warn Leicester of its possible danger. Councillor Biggs knew better. He declared in 1891:[2] "We find small-pox very easy to deal with and the same hospital and staff of officials deal with small-pox as with other infectious diseases." Ex-Mayor Hart had gone even further than Councillor Biggs. As to other infectious diseases he had declared "if there is a case of fever it is dealt with directly and there is no fear of an epidemic." Of course not. That declaration also belongs to 1891. But—and there is much virtue in a but—there was no small-pox in 1891 and we have already admitted that the Leicester system is good so long as there is no small-pox.

How long did this system of using the same hospital and staff for different diseases continue after small-pox broke out? We shall see. Small-pox began to spread in October, 1892, and in November the *Vaccination Inquirer* was engaged in advertising another triumph of the method. The town council was differently occupied. With regard to children convalescing from scarlet fever in the hospital the following is a resolution, as we learn from Dr. Coupland (p. 40), dated Nov. 1st, passed by the Fever Hospital Sub-committee and approved by the Sanitary Committee: "Resolved that the parents of the children in quarantine be advised to attend at the hospital so that they may be informed of the danger of small-pox in the hospital and asked if they wish their children to be brought home to morrow (Wednesday) or would prefer to leave them at the hospital for the present." The form of words adopted here provokes a smile in its comical attempt to preserve some appearance of regard for the liberty of the subject and to conceal the urgency of the need for immediate escape from the hospital. There is a curious resemblance to American methods of voluntary vaccination as indicated by Dr. Rauch to the Royal Commission. Here is the impression which Dr. Rauch's evidence leaves on the reader's mind. An immigrant train as it nears the borders of the State for which the passengers are bound

[1] Vaccination Inquirer, July, 1891. [2] Ibid.

Digitized by Google

is boarded by one or two vaccination officers. They pass from one to another explaining that they are there to carry out vaccination of all who cannot show that owing to small-pox or recent vaccination they do not require it. Everything goes smoothly till they come to some professor of the cult of anti-vaccination. "I understood that vaccination was voluntary here." "So it is," replies the officer, "quite voluntary." "Then I won't be vaccinated." "That's all right," is the reply, "you do just as you please. We'll stop the train and let you out when we get to the boundary of our State. At present we don't want anybody coming into it who is not protected against small-pox." "What is the town at which we will have to get out then?" is the next question. "Oh, there ain't any town; it's a hundred miles from anywhere." "Well, I suppose I must get vaccinated." "Not at all," replies the officer; "we always respect the liberty of the subject in the United States. Vaccination is quite voluntary. Ah, that's the part of your arm you wish me to do it on; thank you. Next, please."

So it was with the Leicester Hospital scarlet fever cases. Their parents were to be told of the danger of small-pox and then they were to do as they pleased. Three weeks later we have an indication of the result. On Dec. 21st we read: "Resolved that the three scarlet fever wards be recommended to be utilised for the reception of small-pox cases."

As regards small-pox this *sauve qui peut* made the best of a bad job. But how was it as regards scarlet fever? Dr. Priestley states in his report for 1893 that within the next two months after the hospital was closed against scarlet fever the cases in the town doubled in number. It appears in that year, if unnotified cases are included, the total ran up probably to 4000. Confining ourselves to notifications, however, Dr. Coupland shows that in 1888 the scarlet fever cases amounted to 132; in 1889 to 409; in 1890 to 516; in 1891 to 794; but in 1892 to 1331; and in 1893 to no less than 2308. Further commentary is not required either on ex-Mayor Hart's statement to the Commission that as regards fever under Leicester management there was "no fear of an epidemic" or on Mr. Biggs's assertion that "we find small-pox very easy to deal with and the same hospital and staff of officials deal with small-pox as with other infectious diseases." As before the Leicester system was one thing small-pox being absent and a very different thing small-pox being prevalent. But we do insist that these several thousand cases of scarlet fever be taken into account in considering the results of Leicester's procedure with regard to small-pox in 1892–93.

THE ROYAL SOCIETY.

ANNIVERSARY DINNER.

THOSE who were fortunate enough to hear the presidential address delivered by Lord Lister on the occasion of the anniversary meeting of the Royal Society on the 30th ult. must have been convinced that the society does important public work apart altogether from the stimulus which it gives to scientific workers to wrest from nature her secrets. It is a fitting occasion, too, to pay tribute to those who have gone from their labours during the year.

The past year in the history of the Royal Society has been a memorable one to which the fact of it being Jubilee year has contributed not a little. The Royal Society in the persons of the officers, vice-presidents, and three former presidents and Lord Lister formed a deputation to the Queen at Windsor to present *in propriâ personâ* the congratulations of the society. These and other incidents, such as the memorial to the Prime Minister urging upon him the importance of establishing in this country a national laboratory in which the testing and verification of instruments of various kinds should be undertaken in a regular and systematic way, afforded Lord Lister abundant material for the annual address. And it was but natural that he should linger upon the close bearing of much of the work done by Fellows of the society to the healing art. The most important reference of this kind was to the work of Dr. Monckton Copeman, whose valuable researches on variola and vaccinia are well known to our readers. Although comparatively little advantage has yet been taken of the system suggested by the lines of this research in this country it has been adopted abroad and the Local Government Board have recently requested their medical officer, Sir Richard Thorne, to inspect the operation of this system abroad with the result that Mr. Chaplin is likely soon to propose legislation for the purpose of giving the full benefits of this valuable process to the country of its discoverer. The advance to which Dr. Copeman's researches have led consisted in the newly found fact that an admixture of glycerine in certain proportions with vaccine lymph derived from the calf had the effect of causing in no long time the disappearance of what were termed the "adventitious microbes" invariably present in that material at the outset without diminishing the efficacy of the lymph for the purpose of vaccination. Lord Lister also announced that his old friend, that distinguished medical officer and gallant soldier, Sir William Mackinnon, the late Director-General of the Army Medical Department, had made a very important bequest to the Royal Society in furtherance of original scientific investigation and research. By his will and codicils dated 1896 and 1897 Sir William Mackinnon, after making certain specific legacies including one of £2000 to the University of Glasgow, bequeathed the whole residue of his property to the Royal Society subject to certain life annuities. The proceeds of the fund are to be applied by the Royal Society for the foundation of such prizes and scholarships for the special purpose of furthering natural and physical science, including geology and astronomy, and for furthering original research and investigation in pathology as the society may think best and most conducive to the promotion of those sciences and of original discoveries therein, such prizes and scholarships to be called after the name of the testator. At the conclusion of Lord Lister's address the society's medals were presented to those recipients whose names have already been announced in this journal.

In the evening the annual dinner was held in the Whitehall Rooms of the Hôtel Métropole, when there was present a very distinguished company including the leaders of all departments of science besides Ambassadors of various countries and representatives of the Houses of Lords and Commons. To the Duke of Devonshire had been allotted the duty of replying to the toast of "Her Majesty's Ministers and the Members of the Legislature." Though his Grace confessed to little scientific attainment his speech proved of the deepest interest to scientific men and to those interested in the progress of science in this country. Touching upon the question as to whether the State can with advantage more directly interest itself in the direction or assistance of scientific inquiry he confessed he was not prepared to express much, but he was led rather to consider the less ambitious object as he termed it—namely, that of making some of the main principles of science more accessible to the main body of the people. He expressed the hope and trust that at no distant time Her Majesty's Government may be able to make proposals and submit measures bearing in some degree upon the subjects just referred to. Amongst these the Duke of Devonshire included such subjects as the creation of a teaching university for London and for the whole country some reorganisation of its secondary education "which is the indispensable foundation of any progress towards higher scientific study." It is needless to add that these pronouncements met with considerable applause.

The proceedings terminated in the usual way, the American Ambassador proposing the "Health of the Royal Society," to which toast the President responded, and he in turn proposed the "Health of the Medalists," to which Professor Forsyth replied with great self-possession and felicity. The final toast, that of "The Guests," was proposed by Lord Kelvin, and Professor Campbell replied. The company then dispersed.

THE CAMPAIGN ON THE INDIAN FRONTIER.

THERE is not much news to be chronicled regarding the progress of the campaign against the frontier tribes. The operations have, as far as the Afridis are concerned, assumed the character of a harassing guerilla warfare. Sir William Lockhart has penetrated to the heart of their country and occupied Tirah and has announced to the Afridis

Digitized by Google

his terms of peace and given them a week in which to submit to them. The cold is beginning to be severe and preparations must be made for winter quarters in case of a more prolonged occupation being necessary, and some of the Sikh regiments, who have done such splendid service and would suffer greatly in health from the cold of a winter's campaign, are returning to India.

But the strategical plan of the campaign, as we have understood it, does not necessarily involve our remaining in the country during the winter and there are indications that this plan will be adhered to. It is announced that Kohat will cease, or has already ceased, to be the base of operations and the Peshawar end of the Khyber Pass will take its place. General Lockhart's object was to get to and pass through the Tirah and Bara valleys and then make his way towards the Peshawar border, joining hands *en route* with General Hammond's column advancing towards the Bara valley from the east from Peshawar by the Khyber route. Sir William Lockhart, in the address he gave to the troops at Maidan, highly commended their bravery and devotion and pointed out very frankly the great natural advantages which the tribes possessed in the kind of warfare in which they were engaged from their intimate knowledge of the ground and from their skill in skirmishing and as rifle shots. He did this in order to inculcate the importance of discipline, controlled fire, mutual support, and the avoidance of straggling. Of course he did not omit to add his assured confidence in the success of his force, and it is a noteworthy indication of a general's entire belief and trust in the troops under his command that he had no misgivings about putting the position thus plainly before them. He knew the men with whom he was dealing. The troops composing the expeditionary columns have had most laborious marches through the defiles and over mountainous passes and have had to encounter a good deal of hardship due to the great diurnal variations of temperature, the hard work by day and disturbed rest at night, owing to the nightly firing and occasional "rushes" of the tribes, but their health and spirits have remained excellent. As illustrative of the liability of native troops from the plains of India to contract and die from respiratory diseases as compared with European troops we may take the figures in the blue-book on the "Sanitary Measures in India" recently issued. Respiratory diseases are the chief cause of death and in 1895 no less than 42 per cent. of all the deaths in the native army were due to them. Much of the pneumonia was attributable to the exposure endured by the regiments on active service in Waziristan and Chitral. The admission and death ratios were highest in the Indus valley and the hills, and the percentage of pneumonia to total deaths was there also highest. Both in the Indus valley and in the hills pneumonia was most prevalent in the cold months, and the same was the case for India as a whole. European troops suffer much less on field service than the natives, probably because they are more accustomed to cold, because they are better clad, and more nutritiously fed. Many medical officers serving with native regiments on the frontier are of opinion that the pneumonia is often of an infectious type and all seem agreed that malaria-saturated or scurvy-tainted men exposed to chill are peculiarly vulnerable in this respect.

Some progress towards peace has been made. The Tochi expedition appears to be settled, things are quiet in the Kurram, the Malakand expedition is over, the Ali Khel Orakzais in Mastura Valley have submitted and are paying the fines imposed upon them, and Sir William Lockhart is now waiting to see the result of his proffered terms to the Tirah tribesmen. If they are accepted, and according to the latest intelligence there appears to be some hope that they will be accepted, the troops will forthwith commence their return marches to India by columns. The "politicals" will, we feel pretty sure, try to effect a settlement if only to avoid the ruinous drain of a prolonged occupation on the Indian exchequer. General Westmacott's brigade has advanced to Duatoi after having traversed some miles of the worst defiles they have yet had to cross. It may be mentioned that the Lee-Metford bullet, as modified in India, has proved much more effective as regards "stopping power" than the missile which it replaced. According to the *Times of India* of Nov. 6th the deaths from disease in General Blood's Malakand force since Sept. 6th, including those at the base hospital at Nowshera, had only been—British seven, native five. This shows how healthy the troops have been and reflects much credit on the sanitary and medical arrangements. Intelligence from the Indian frontier regarding the campaign fixes what is to be the future programme. From the Bagh camp as a centre detached columns will march through the country, equipped with the lightest amount of baggage, stores, and food supplies. The latest news is of a more favourable character owing to the submission of several of the Afridi tribes. If the remaining tribes refuse to accede to the terms offered them the force will winter in a standing camp in suitable and specially selected position, probably near Barkai. According to some accounts the position of the Ameer of Afghanistan is a very difficult one, for his friendly policy towards the Indian Government is not popular with his own people or, of course, with the Afridi tribes. It is, to be earnestly hoped that a satisfactory settlement may be soon arrived at, for the situation whether regarded from a military or political point of view has grave difficulties. The positions taken by us cannot for sanitary, financial, and transport reasons be held during the winter, and when the troops evacuate them and return towards India it may be confidently expected that they will be subject to attacks by the tribesmen; and on the other hand to undertake another punitive campaign will be merely doing the work over again at ruinous cost. The sick and wounded are, we are glad to learn, doing well. The commissariat and medical arrangements during the campaign have by all accounts been very good.

THE BATTLE OF THE CLUBS.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND AND MEDICAL AID ASSOCIATIONS.

AS we reported in THE LANCET last week, Mr. W. G. Dickinson, the honorary secretary of the Society of Members of the Royal College of Surgeons of England, moved a resolution at the thirteenth annual meeting of the Fellows and Members of the College, held on Nov. 18th last, asking the Council of the College "..... to make a clear pronouncement for the information of Fellows and Members that the acting by qualified medical practitioners as the paid officials of any institutions which tout and canvass for patients or which allow the well-to-do classes to take advantage of rates of payment arranged to meet the necessities of the poor is 'disgraceful in a professional respect' and deserving of censure." Mr. Dickinson pointed out the widespread public and professional evils induced by Medical Aid Associations and other companies trading in medical attendance and was able to adduce examples in the procedure of other corporations in support of his resolution. The Royal College of Physicians of Ireland had expressed disapproval of their Licentiates accepting appointments to medical aid associations; the Royal College of Surgeons in Ireland had on one occasion at any rate represented to a Licentiate the impropriety of being associated with a canvassing business; and the Royal College of Physicians of London had declared association with institutions of this sort to be undesirable on the part of their Fellows and Members.

Mr. Dickinson's motion was carried, the President saying that if particular instances of canvassing were brought before the Council the cases would be considered very carefully. There should be no difficulty in giving the Council a good deal to consider.

EASTBOURNE PROVIDENT MEDICAL ASSOCIATION.

A meeting of the medical profession in Eastbourne was recently held to receive the second annual report of this association. The report showed that the year had been one of steady progress. The number of members had grown to 4153 as against 3689 at the date of the last annual report. The total amount received in members' payments for the year had been £743, an increase of 23½ per cent. upon last year. £624 had been distributed amongst the acting staff—a total higher than last year's by £130. The working expenses had been covered by a charge of something over 16 per cent. of the money collected. Only one instance of a family financially ineligible having gained admission to the association had been brought to the notice of the committee, and they were, after due inquiry, removed from membership. We congratulate the association upon their sound work; local organisations of this sort should have no difficulty in holding

Digitized by Google

their own against the medical aid societies, supplying as they do better attendance at much the same aggregate cost, while the money is received by the people who do the work.

THE WANDSWORTH PROVIDENT DISPENSARY.

We have received the rules of the Wandsworth Provident Dispensary, the object of which institution is "to enable the working classes to insure to themselves and their families efficient medical advice and medicine during illness by their own weekly payments, *commenced in time of health*, aided by the contributions of other inhabitants." There are certain points about the rules which call for commendation, although in other respects the dispensary sins in company with most medical aid societies. For example, under Rule IV. the consulting medical officer, together with the treasurer and secretary, becomes an *ex-officio* member of the Committee of Management, whose functions are to be "entrusted with the general management of the institution, the appointments and dismissal of its officers and the superintendence of its financial affairs." We are glad to see that the resident medical officer, whose services constitute the whole and only benefit which the dispensary offers to its members, will have someone of medical knowledge to represent professional views on the Committee of Management by which he is controlled. He is himself probably in a far better position to help the Committee of Management than ever his consultant-colleague can be, but presumably he can inform that gentleman of the things that it is necessary for him to know. We note with regret that no wage limit is imposed upon the members. We have reason to believe that this dispensary is well and fairly managed, but we would point out to those in authority over its working that to have no wage limit and to seek aid from "other inhabitants" than the members is to invite abuse of the charity.

A QUESTION OF COMPARATIVE IMPORTANCE.

A correspondent in the Isle of Man sends us the following extract from the *Isle of Man Examiner* of some weeks ago:—

"The minutes of the Stores Committee [of the town council of Douglas] included the following:—

"Resolved: That the tender of Mr. T. S. Atkinson, Finch-road, quoting 3*s.* 6*d.* per horse per month for shoeing, including leathers, frosting extra, be accepted.

"Tender for supplying veterinary attendance and medicine for the ensuing year submitted and considered. Resolved: That the tender of Mr. T. S. Atkinson offering to supply veterinary attendance and medicine for the horses for a period of twelve months at £1 1*s.* per horse per annum, examinations as to soundness to be extra, be accepted.

"The minutes were adopted upon the motion of Councillor Cubbon, seconded by Councillor Moore."

An accompanying letter informs us that from the balance-sheet of a friendly society before him he learns that "a leading practitioner of the district attends members, provides medicine, and, if ordered, stimulants at the rate of 2*s.* 6*d.* per member per annum, a very small proportion of which is levied from the members themselves." We, like our correspondent, are very glad that Mr. Atkinson's services are appreciated at their true worth, but the difference between the price paid for the medical charge of a horse and that paid for the medical charge of a man is a little sensational, even though the quadruped is the larger animal.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6409 births and 4258 deaths were registered during the week ending Nov. 27th. The annual rate of mortality in these towns which had been 19·0 and 18·6 per 1000 in the two preceding weeks rose again last week to 20·2. In London the rate was 21·0 per 1000 while it averaged 19·7 in the thirty-two provincial towns. The lowest rates in these towns were 11·0 in Cardiff, 12·5 in Croydon, 13·1 in Portsmouth, and 15 5 in Hull; the highest rates were 23·7 in Sheffield, 24·1 in Burnley, 28·2 in Oldham, and 28·6 in Swansea. The 4258 deaths included 552 which were referred to the principal zymotic diseases, against 461 and 462 in the two preceding weeks; of these, 218 resulted from measles, 97 from diphtheria, 70 from whooping-cough, 70 from "fever" (principally enteric), 58 from scarlet fever, and 39 from diarrhœa. No death from any of these diseases was recorded last week in Brighton, Plymouth, or Derby; in the other towns they caused the lowest death-rates in Cardiff and Croydon and the highest rates in Oldham, Burnley, Halifax, and Blackburn. The greatest mortality from measles occurred in London, Birmingham, Huddersfield, Oldham, Halifax, Blackburn, and Swansea; from scarlet fever in Burnley; from whooping-cough in Sheffield; and from "fever" in Bristol, Preston, and Birkenhead. The 97 deaths from diphtheria included 63 in London, 8 in Leeds, 4 in West Ham, 4 in Burnley, and 3 in Manchester. No fatal case of small-pox was registered last week either in London or in any other of the thirty-three large towns; and no small-pox patients were under treatment in any of the Metropolitan Asylum Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on Saturday last, Nov. 27th, was 3818, against 3680, 3777, and 3792 at the end of the three preceding weeks; 375 new cases were admitted during the week, against 339, 460, and 397 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London which had been 420 and 414 in the two preceding weeks rose again to 471 last week and were 36 above the corrected average. The causes of 59, or 1·4 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bradford, Leeds, Newcastle-upon-Tyne and in thirteen other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Leicester, Liverpool, and Preston.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns which had been 20·1 and 18·5 per 1000 in the two preceding weeks rose again to 19·5 during the week ending Nov. 27th, but was 0·7 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 14·5 in Leith and 17·5 in Dundee to 22·2 in Aberdeen and 25·4 in Greenock. The 581 deaths in these towns included 23 which were referred to whooping-cough, 22 to diarrhœa, 12 to scarlet fever, 10 to measles, 5 to diphtheria, and 2 to "fever." In all, 74 deaths resulted from these principal zymotic diseases, against 64 and 62 in the two preceding weeks. These 74 deaths were equal to an annual rate of 2·5 per 1000 which was slightly below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough which had declined from 16 to 10 in the three preceding weeks rose again to 23 last week and included 15 in Glasgow. The deaths referred to scarlet fever which had been 18, 11, and 8 in the three preceding weeks rose again to 12 last week, of which 5 occurred in Glasgow, 3 in Dundee, and 2 in Edinburgh. The 10 fatal cases of measles showed a decline of 2 from the number in the preceding week and included 9 in Glasgow. The deaths from diphtheria which had been 6 and 4 in the two preceding weeks were 5 last week, of which 2 were recorded in Glasgow and 2 in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had been 161 and 145 in the two preceding weeks further declined to 123 last week and were 49 below the number in the corresponding week of last year. The causes of 35, or more than 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin which had been 19·8 and 23·3 per 1000 in the two preceding weeks further rose to 25 4 during the week ending Nov. 27th. During the past eight weeks of the current quarter the death-rate in the city has averaged 23·2 per 1000, the rate during the same period being 18·0 in London and 18·8 in Edinburgh. The 170 deaths registered in Dublin during the week under notice showed an increase of 14 upon the number in the preceding week and included 20 which were referred to the principal zymotic diseases, against 24 and 10 in the two preceding weeks; of these, 12 resulted from "fever" (principally enteric), 4 from diarrhœa, 3 from scarlet fever, 1 from whooping-cough, and not one either from

Digitized by Google

small-pox, measles, or diphtheria. These 20 deaths were equal to an annual rate of 3·0 per 1000, the zymotic death-rate during the same period being 3 3 in London and 1 6 in Edinburgh. The deaths referred to different forms of "fever" which had been 8, 10, and 6 in the three preceding weeks rose again to 12 last week. The fatal cases of scarlet fever which had been 8 and 1 in the two preceding weeks rose to 3 last week. The 170 deaths in Dublin last week included 28 of infants under one year of age and 36 of persons aged upwards of sixty years; the deaths of infants showed a decline while those of elderly persons corresponded with the number in the preceding week. Four inquest cases and 4 deaths from violence were registered; and 71, or more than a third, of the deaths occurred in public institutions. The causes of 11, or more than 6 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-MAJOR MACPHERSON is directed to investigate the cause of the recent outbreak of scarlet fever at Caterham Barracks. Surgeon-Lieutenant-Colonel Powell is appointed to the medical charge of the 18th Regimental District. Surgeon-Captain Weir, Surgeon-Lieutenant Hewetson, and Surgeon-Lieutenant Clements are ordered to be ready to start shortly for India; Surgeon-Lieutenant S. A. Archer is also held in readiness for service in India. Surgeon-Major Battersby takes over the charge of Station Hospital, Dover Castle, and Surgeon-Major White takes over medical charge of the Staff and Departments, Dover.

NAVAL MEDICAL SERVICE.

Surgeon George Allan has been allowed to withdraw from Her Majesty's Naval Service with a gratuity.

MILITIA MEDICAL STAFF CORPS.

The under-mentioned gentlemen to be Surgeon-Lieutenants:—Alfred Hugh Benson and William Fletcher.

VOLUNTEER CORPS.

Artillery: 1st Ayrshire and Galloway: Surgeon-Lieutenant J. G. Thomson resigns his commission. *Rifle:* 2nd Volunteer Battalion the Duke of Wellington's (West Riding Regiment): Surgeon-Lieutenant R. C. Brown resigns his commission. The under-mentioned gentlemen to be Surgeon-Lieutenants:—Louis Demetriadi and Henry William Williams. 3rd (Duke of Connaught's Own) Volunteer Battalion the Hampshire Regiment: Surgeon-Lieutenant C. S. Ticehurst to be Surgeon-Captain.

NAVAL MEDICAL EXAMINATION.

The under-mentioned gentlemen, who competed on Nov. 22nd and following days at Examination Hall, Victoria Embankment, for appointment as surgeon in the Royal Navy, have been granted commissions:—

VOLUNTEER AMBULANCE SCHOOL OF INSTRUCTION.

The following officers have accepted the invitation of the President and staff of the school to be present at the distribution of prizes and Bohemian entertainment which will take place at St. Martin's Town-hall, Charing-cross, on Thursday, Dec. 9th, viz.:—Major-General H. Trotter, commanding the Home District; Surgeon-Major-General J. Jameson, M.D. Glasg., Director-General Army Medical Department; Surgeon-Major-General J. B. Hamilton, M.D. Dub., Principal Medical Officer Western District; Surgeon-Colonel T. O'Farrell, M.D. R.U.I., Principal Medical Officer; and Colonel W. H. Mackinnon, Assistant-Adjutant-General Home District. The proceedings will commence at 8 30 P.M. precisely and a large number of the commanding officers of Yeomanry and Volunteer corps of the Home District have signified their intention of being present.

THE FRENCH IN MADAGASCAR.

The news from Antananarivo regarding the French occupation of Madagascar is not satisfactory. It appears that several of the French posts established in the Sakalava district have been attacked with the loss in some cases of a number of officers and men forming the garrison of these posts. A number of rifles and a large quantity of ammunition have fallen into the hands of the rebels. Reinforcements are being rapidly forwarded and the French will no doubt speedily stamp out the rebellion but not without incurring, it is feared, a good deal of sickness and loss of life on their part from malarial fevers and dysentery, owing to the fact that this is the most unhealthy season of the year in that climate.

THE GALLANTRY OF SOME OF THE NATIVE TROOPS IN INDIA.

The loyalty and devotion of the native army engaged in the frontier war in India have afforded extreme satisfaction. There have been several instances of great bravery on the part of native soldiers, in the Sikh and Goorkha regiments more especially, which thoroughly deserve recognition. It seems to us that examples of unusual gallantry entitle the individuals concerned to share in the honour and glory of their deeds and we hope to see a few soldiers of the native army who have been conspicuous for any act of heroic gallantry recommended for the Victoria Cross and that this tribute may be conferred upon them in a few cases where it is thoroughly merited.

THE SOUDANESE MUTINY.

News received from Fort Lubas and dated Oct. 24th gives an account of the great gallantry of Dr. Macpherson in carrying off Mr. Jackson, the Acting Commissioner, when badly wounded by the mutineers, to a place of safety under a heavy fire. Dr. Macpherson was himself wounded in the shoulder at the time of his succouring the Acting Commissioner.

THE SICKNESS IN THE RIFLE BRIGADE IN INDIA.

The *Times of India* of Nov. 13th states that the Rifle Brigade had arrived at Rawal Pindi where they made a halt for three days before proceeding to Umballa. It is reported that there have recently been 73 deaths in the regiment and that probably 100 men will require to be invalided.

DEATHS IN THE SERVICES.

Brigade-Surgeon-Lieutenant-Colonel North, 1st Madras Lancers, from cholera at Sanganakulli, in the Madras Presidency.

The *Army and Navy Gazette* says: "The Government of India has recently been called upon to decide a point affecting officers of the Indian Medical Service. The question raised had reference to the right of an officer of the Indian Medical Service in civil employ to demand a fee when called into a consultation on a sick military officer by the medical officer in charge of the case. It has been decided that an officer entitled to gratuitous medical attendance is also entitled to gratuitous advice from a medical officer in the employment of the Government called into consultation by the medical officer who is, in accordance with the regulations, in charge of the case. It is only when an officer declines the attendance of the medical officer provided by the Government and calls in another medical officer to attend him in illness that the usual fees can be claimed by the latter."

The promotion of Brigade-Surgeon-Lieutenant-Colonel Caldecott, I.M.S., to the rank of Surgeon-Colonel removes him from Central India where, according to the *Pioneer Mail*, he has served for a long time and enjoyed a deservedly high reputation for his surgical skill as well as his administrative ability. The Indore Charitable Hospital, the scene of his hospital work, is said to be a model of what such institutions should be. He was not only well known in Indore but throughout Central India, and in every native State will the loss of his services be deplored. The amount of good done by medical officers of this stamp in strengthening our position with the native population is not easily estimated.

TROWBRIDGE COTTAGE HOSPITAL.—The annual report of the Trowbridge Cottage Hospital shows that thirty-three patients were admitted during the past year.

"Audi alteram partem."

UNQUALIFIED ASSISTANTS.

To the Editors of THE LANCET.

SIRS,—The General Medical Council have at last declared the employment of unqualified assistants to be "infamous conduct in a professional respect," but having done so it should I think go further and as far as possible protect not only the public but the qualified practitioner from the hosts of unqualified men up and down the country who unfairly and illegally pose as qualified. Hitherto this task has been undertaken, but only to a limited and half-hearted extent, by practically one body—viz., the Society of Apothecaries. In the analogous case of the law, however, we do not find our legal brethren so slow to move in the matter of protecting their qualified men against the insidious attacks of legal quacks. If the General Medical Council has no powers in the matter by their several Acts of Parliament it is surely time that these were obtained in the interests both of the profession and the public.—I am, Sirs, yours faithfully,

Swinton, Nov. 27th, 1897. SAMUEL HOSEGOOD.

To the Editors of THE LANCET.

SIRS,—I have perused the report of the proceedings of the General Medical Council in THE LANCET of Nov. 27th and I am lost on account of the vague, opposite, and indefinite expressions of opinion by the individual members of the Council as to what the appendix introduced by Dr. MacAlister really means. To begin with, on receipt of the appendix notice is a practitioner supposed to have to wade through these various speeches and digest them for his own mental enlightenment or confusion? The appendix concludes as follows: "But the foregoing notices do not apply so as to restrict the proper training and instruction of *bonâ-fide* medical students and pupils or the legitimate employment of dressers, dispensers, and *surgery attendants* under the immediate personal supervision of registered medical practitioners," and while I observe endless discussion — without any definite decision being arrived at—as to when, where, and how a man is a *bonâ-fide* student or pupil not one word do I note as to what is, or what is not, the limit of work of "a surgery attendant." I may say that I am in general practice and keep a qualified assistant and also a gentleman—full curriculum and son of a deceased hospital staff practitioner—whom at present I would describe as "a surgery attendant." We all live under the same roof; the attendant keeps my books, dispenses, and stays in the surgery while the qualified assistant and myself are out on our "rounds." He also attends a few midwifery cases when the qualified assistant and myself are otherwise engaged. He does not pay visits in the ordinary course of events; if a message comes when the qualified assistant and myself are out it awaits our return—unless there is a pressing and urgent call. Am I to understand that if word is sent to my house that one of my patients is in the position of imminent danger from miscarriage, hæmorrhage, precipitate labour, or accident during the absence of myself or assistant such a competent "attendant" is to shut the door and decline to act in the emergency, while the herbalists and midwives in the district and the very policemen in the street or some factory operative who have attended a superficial course of ambulance lectures are fit and proper persons to interfere in the hundred and one cases which arise in the everyday life of our manufacturing towns. It is all very well for the consultant majority of the General Medical Council to sit in philosophic arm-chairs and draw up theoretical, vague, and indefinite resolutions, but I, as a general practitioner and a practical man, would ask for something more definite. Until then I do not know what my position is — whether I am a law-abiding citizen or an "infamous" one! Finally, is it the intention of the General Medical Council to drive from within the ranks of the profession a whole army of deserving men, although unqualified, who are in common with their principals actuated by the ethic and moral code of a liberal profession, to swell the decidedly better paid outside ranks of unqualified persons and quacks over whom the Council not only have no control but judging by their past and present action do not seek to have control by those powers which are possessed by other professions?

I am, Sirs, yours faithfully,

Nov. 29th, 1897. G. P.

To the Editors of THE LANCET.

SIRS,—The resolution recently passed by the General Medical Council in regard to the employment of unqualified assistants is truly hard if not unjust. I know many who like myself have had a chequered career for want of other necessaries than brains and under the old regulations we were allowed and encouraged to prosecute our studies by the help of a qualified principal. The penalties set forth for a breach of this rule are so plain and so severe that it means a speedy extinction of the unqualified assistant and a great hardship upon many a principal whose slender means may not be sufficient to justify the engagement of a qualified assistant. Hundreds of married men in colliery districts will have to seek other employment.

If the General Medical Council would move in the matter of suppressing the quackery practised by so-called "oculists" and "aurists," abortionists, truss-specialists, and swindling pill vendors and leave the *bonâ-fide* unqualified assistant alone they would earn the gratitude of thousands of practitioners and especially of one who is not ashamed to say that had this stringent clause been inserted six years ago he would not have been able to sign himself

Yours faithfully,

Nov. 30th, 1897. M.B. LOND.

To the Editors of THE LANCET.

SIRS,—My son and I are partners and for many years have had an unqualified assistant who acts as dispenser and when very busy or in an emergency visits. The assistant registered many years ago as a student, but from pecuniary difficulties has never been in for his examinations; he has had ample experience both in England and Scotland and is quite capable of taking charge of any ordinary case. Are we acting in an "infamous" manner or going against the law of the land? I may say that we have three or four times tried a qualified man for the post, but they were always a failure, not because of any faults in practice, but because they thought that they ought to be more entrusted with patients and in fact got above their position. What am I to do?

I am, Sirs, yours faithfully,

Dec. 1st, 1897. MEDICUS.

THE ANNUAL MEETING OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

To the Editors of THE LANCET.

SIRS,—In your report of this meeting you omit to notice the fact that the Council of the College passed in 1893 a resolution (which I quoted) supposed by many to refer to medical aid associations. This resolution declares it to be degrading to the profession and disgraceful to the College that Fellows or Members should be connected with "trading institutions for the treatment of disease." This would be considered by most people a good definition of a medical aid association as usually conducted by laymen. It appears, however, that it really referred to the Harness Belt Company. My point was that if the Council could, without hesitation or difficulty, pass such a resolution as this in 1893 there can be no valid reason why it should not pass a similar one in 1897. There is every reason why it should do so since its obstinate refusal has already led to the scandal of medical aid appointments being resigned by Members or Licentiates of other colleges whose councils have had the courage of their convictions and to their places being immediately taken by Members of the Royal College of Surgeons of England.

It is no doubt satisfactory that the Council is willing to consider a case in order to determine whether it comes under By-law XVI., but as it has already decided that it has no power to question the legal position of the holders of these appointments the probable result of such consideration may be easily foreseen. It comes to this; every member of the Council knows that what is going on all over the country is a scandal and a disgrace to the profession several have said so publicly; and yet on account of some absurd technicality they are afraid to express a collective

Digitized by Google

opinion which they know would have a powerful effect in checking the evil. Such an opinion may be called "pious," but it would govern the policy of the Council, would act as a warning to offenders, and would indicate a determination to use every possible means to purge this College of all complicity with one of the greatest scandals of the day.

I am, Sirs, yours faithfully,

Nov. 29th, 1897. W. G. DICKINSON.

"MORALS AND THE STAGE."

To the Editors of THE LANCET.

SIRS,—In an annotation with the above heading in THE LANCET of Oct. 2nd you say: "We should doubt ourselves whether crime was ever prompted by either a poster or a stage representation," and you also quote Sir Henry Irving as having asked at a complimentary dinner at Cardiff, "How many wives had owed a violent death to the pernicious example of Shakespeare in *Othello*"? While I agree with you as to posters, which produce a mere passing impression, and are therefore as highly coloured as possible with that object in view, I think that a stage representation is a very different thing and that in the case of tragedies the more powerful the play the more is the attention fixed and the more likely are the mental images to remain deeply impressed in the brain of the spectator.

Some years ago I had to do with a case of murder where the idea of strangulation was directly prompted by a theatrical representation of *Othello*. It was the case of a young Italian who insured the life of his servant to his own benefit and after waiting a couple of months smothered him in his bed one night. At his trial the criminal calmly remarked that he had lately seen (*twice* he actually went, probably with the object of perfecting his method) the opera of *Othello* and that he "only did to the young man what Othello did to Desdemona," and he also confessed that in the very act of smothering his victim "the scene in the theatre was vividly before him as it was before him now" ("*Tuve y tengo presente lo que hizo Otello con Desdemona*" is what he actually said in Spanish). There is no doubt that in this case the crime of strangulation was directly suggested to the would-be murderer by a stage representation of *Othello*. This is one case at any rate for Sir Henry Irving to ponder over. The whole case of this Italian was especially rich in medico-legal interest, but I must not encroach any more on your valuable space.

I am, Sirs, yours faithfully,

GEORGE MACKERN, M.D. Lond.

Buenos Aires, Argentine, Nov. 4th.

"THE DISINFECTION OF CLOTHING BY HEAT."

To the Editors of THE LANCET.

SIRS,—I have not the good fortune to be personally acquainted with Professor Delépine, but judging from the courteous wording of his letter I feel confident that he will acquit me of plagiarism when I assure him that until to-day I was absolutely ignorant that anything like my steam disinfector had ever been in use before. I think that there is some excuse for this inasmuch as I have not noticed any mention of it in THE LANCET; nor in the appendix on Steam Disinfectors in Applied Bacteriology (edition 1897), by Pearmain and Moor; nor in the chapter on Disinfection in the Manual of Infectious Diseases (edition, June, 1896), by Goodall and Washbourn; nor in the Theory and Practice of Hygiene (edition 1896), by Notter and Frith. Mr. Bailey and myself had been working at the subject for several weeks, but the heating power was always the stumbling-block, and although the sight of painters with an "Etna" in hand scraping old paint off doors was familiar enough the idea of using volatilised petroleum never occurred to me until Mr. Bailey suggested it. Curiously enough, a week or two before I had begun to think about making a machine a notice under the head of "New Inventions" appeared in THE LANCET of May 29th, 1897, describing "a wickless oil stove with smokeless flame" (made by the same firm which makes the "intensive oil-furnace" shown in the illustration to my paper) and referring to the production of this flame as an "attainment of some importance." This notice escaped my attention probably because I had not at that time any use in view for such a stove. With regard to the similarity in shape, dimensions, and the amount of water necessary which Professor Delépine points out, my opinion is that if he put the principle of heating by volatilised petroleum into the heads of ten men and told them to make a steam disinfector nine of them would make one pretty much the same in shape and dimensions and would come to the same conclusion as to the amount of water necessary as Professor Delépine and myself. With regard to Mr. Walter Bernard's letter I have looked up THE LANCET of May 16th, 1896, and I find a short account of an apparatus for disinfection by exposure to fumes of heated eucalyptus and carbolic acid. There is no mention of volatilised petroleum or steam at boiling water temperature and without steam at 100° C. I feel convinced he will not get eucalyptus and carbolic acid fumes to penetrate through woollen fabrics in any reasonable time; if, on the other hand, he can get steam at that temperature throughout his disinfecting chamber he can then dispense with those agents altogether.

I am, Sirs, yours faithfully,

Nov. 27th, 1897. A. F. MESSITER.

To the Editors of THE LANCET.

SIRS,—Mr. Messiter has shown me Professor Delépine's letter to you and his own answer. I beg to confirm all that Mr. Messiter says and to say that the use of volatilised petroleum was suggested by myself alone without ever having seen or heard of any similar disinfection apparatus. The similarity in shape and dimensions may be accounted for by the fact that galvanised iron is sent out in sheets 6 ft. by 2 ft. 6 in. The height of the chamber without the lid is 2 ft. 6 in. and 6 ft. gives diameter of 21 inches after allowing for seams.

I am, Sirs, yours faithfully,

Epworth, Nov. 29th, 1897. ALFRED BAILEY.

"THE MECHANISM OF DEATH FROM CHLOROFORM."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Nov. 13th Surgeon-Lieutenant Lane criticises my paper on the Mechanism of Death from Chloroform. It would have been fairer to me had he read my paper more carefully, giving the expressions used in it their proper value, and it would have been still better had he reserved his remarks until he could have referred to my previous paper and Dr. Snow's book from which Cases 6 and 7 are taken.

The reports of the cases coming at second-hand are not full, but the information afforded is enough for the immediate purpose and greater than Surgeon-Lieutenant Lane seems to appreciate. In describing Case 2 I advisedly employ the terms "breathing deeply" and "free respiration" expecting these words to be taken at their current value, as indicating that air was freely entering the chest and trusting your readers to credit me with a knowledge of the difference between "free" and "obstructed" respiration. Yet Surgeon-Lieutenant Lane does not know "whether air was entering the chest or not!" In Case 3, scanty as the information is, it is enough to emphasise the fact that there may be free respiration at a period when the circulation has practically ceased as shown by the absence of bleeding on incision. As regards Case 7 Surgeon-Lieutenant Lane says "the clinical picture is familiar enough. It is that of a man whose air-passage is obstructed, say, by the root of his tongue." Has Surgeon-Lieutenant Lane ever known a patient with his air-passage obstructed in this fashion take long, deep inspirations or die under the circumstances described?

In Case 1 I agree with Surgeon-Lieutenant Lane that similar symptoms could be produced by shock—that is practically the point to which I have already drawn attention. In this particular instance I consider the symptoms were caused by the chloroform and precipitated by the sudden raising of the head further depleting the nerve centres of blood. May I remind Surgeon-Lieutenant Lane that in the condition known as "shock" we have extreme lowering of the blood pressure. My contention is that an equal lowering of the blood pressure may also be produced by chloroform (indeed is produced) and the outward manifestations of the occurrence of this condition depend upon the degree of narcosis the patient is in at the time.

I am, Sirs, yours faithfully,

Manchester, Nov. 24th, 1897. ALEXANDER WILSON.

"A NOTE ON CYCLING."

To the Editors of THE LANCET.

SIRS,—As a cyclist of over a quarter of a century (I first rode in 1872) I feel I must challenge Dr. Campbell's statements regarding posture and reasons given for less fatigue in cycling compared to walking.

First, regarding posture, it stands to reason that if the dorsal curve of the spine is exaggerated the ribs must necessarily come closer together and so impede thoracic movements. Diaphragmatic respiration is encouraged therefore. The intervertebral discs are pressed upon and, in proportion to the length of time the position is assumed, they are made wedge-shaped, the spinal ligaments are modified by vibration to this position, and the result is kyphosis bicyclistarum in those cases where Dr. Campbell's graceful curve of back is made to harmonise with the wheel rims for hours and days together. I have ridden all sorts of "safeties," various makes of "ordinary" (varying from a 56 in. to a 62 in.), the old Ariel, and the iron-rimmed "bone-shaker," and my experience is that the intervertebral discs, though capable of much recuperation after malposition in riding, are very sensitive to jarring and vibration. To ride an iron-rimmed bone-shaker with a curved back would be fraught with dire discomfort subsequently. My theory is this—that so long as the *lumbar* curve of the spine is a forward one—i.e., so long as its convexity is anterior—it is quite allowable to bend the spine forward as a whole, so that the resistance to the atmosphere is diminished; but if the lumbar curve is obliterated and made continuous with the dorsal one the position is faulty. I speak with more authority than most cyclists for I have made many trials and being 6 ft. 6½ in. in height a faulty position of the spine in my case soon "tells."

Regarding the second point, as to increased endurance, the whole hinges upon carrying *versus* rolling a weight. In cycling we roll our own weight; gearing gives leverage (third order) and diminishes muscular movements; ball-bearings diminish friction, and pneumatic tyres are to the cycle what steel rails are to the train and locomotive. I am willing to admit Dr. Campbell's comparative anatomy, but if the erect position were such an effort to maintain as he suggests, then I for one ought to find walking a most arduous exercise. In practice I do not; I can walk all day and do a mile in eleven minutes, therefore although Dr. Campbell's suggestions regarding diminished distance from head to feet may apply in some cases he cannot lay it down as a universal fact.

I am, Sirs, yours faithfully,
G G. GIDLEY, M.R.C.S. Eng., L.R.C.P. Lond.

Cullompton, Devon.

A QUESTION OF TITLE.

To the Editors of THE LANCET.

SIRS,—The modern development of professional ethics has quite determined that a practitioner shall not advertise himself as a Doctor of Medicine when he is a Licentiate of the College of Physicians only and so on. Is it not quite a parallel indiscretion for a hospital to advertise itself as the "Cancer Hospital" when members of its staff admit cases of uterine myoma and perform "panhysterectomy" without making it clear that they at least had the excuse of a mistake in diagnosis?

I am, Sirs, yours faithfully,
LAWSON TAIT.

Newhall-street, Birmingham, Nov. 26th, 1897.

"SURGICAL SYMPTOMS IN CONNEXION WITH FILARIA SANGUINIS."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Oct. 9th last is an annotation on an interesting paper on Filarial Diseases of the Lymphatics, read by Surgeon-Lieutenant-Colonel W. K. Hatch before the Bombay Medical and Physical Society. Everyone must sympathise with Surgeon-Lieutenant-Colonel Hatch in the unfortunate issue of the case upon which he reluctantly operated, but at the same time the evidence afforded by the symptoms point to death having been due to some cause unconnected with the disease of the lymphatics. In any case I submit that it is hardly rational to condemn this operation on the results of an isolated case.

In an article on this subject[1] I drew attention to the fact that twenty-four operations of this nature had been performed during the last seven years in the Madras General Hospital and in none of these cases did any serious symptoms arise. In carrying out the operation care should be taken as far as possible to secure all the lymphatic vessels before they are divided. If, in spite of this precaution, leakage should occur, firm pressure should be applied by means of a sponge which is included within the dressings. If these precautions be adopted the wound will generally heal by first intention. Cases of filarial lymphangiectasis of the spermatic cord are treated in the same manner and with the same precautions. Experience has confirmed me in the opinion that operative measures are called for in many cases of lymphangiectasis of filarial origin. Not only is there a prospect of securing some of the parental worms, a result which I have in several instances achieved, but there is also the prospect of relieving the patient from the serious annoyance caused by recurring attacks of inflammation. There are no doubt certain cases in which there have been attacks of chyluria or in which there are other evidences to show that the seat of obstruction is at some point high up in the lymphatic system that is not suitable for operation. Putting such cases aside the operation is one which, in my opinion, may be confidently recommended as holding out a prospect of relief to the patient and one which involves but little risk.

I am, Sirs, yours faithfully,
J. MAITLAND, M.D. Edin.,
Surgeon-Lieutenant-Colonel.

General Hospital, Madras, Nov. 11th, 1897.

ON A SOPHISTICATED SYRUP OF FERROUS IODIDE.

To the Editors of THE LANCET.

SIRS,—May I be allowed to call attention to the fact that much of the syrup of ferrous iodide now found in the pharmacies contains hypophosphorous acid in appreciable quantities. The responsibility for this seems to rest on certain London firms who prepare syrupoids or solutions for the preparation of these syrups alleging them to produce more elegant syrups than the methods of the Pharmacopœia. The presence of the hypophosphorous acid being quite unlooked for may explain how it is that syrupus ferri iodidi so often produces gastric troubles in young children.

I am, Sirs, your obedient servant,
Dublin, Nov. 29th, 1897. J. C. MCWALTER, L.R.C.S. Irel.

"THE IMMEDIATE TREATMENT OF THE DEFORMITY OF SPINAL CARIES."

To the Editors of THE LANCET.

SIRS,—The paper which we read on this subject before the Clinical Society of London on Nov. 12th was brought forward by us for certain specific purposes which were therein detailed—viz., to demonstrate the feasibility and safety of this method in suitable cases. The question of ultimate results was one with which a paper founded upon cases of four months' duration could not pretend to deal nor did it attempt to do so. As such it was accepted for reading. It is a matter of great satisfaction to us that you in your editorial article of Nov. 20th and in common with other medical periodicals have granted our theses and in the following words: "(1) That angular curves of the spine can very generally be straightened by the exhibition of an amount of force well within the limits of safety; (2) that this treatment is not attended with grave immediate danger if carried out with due care; and (3) that curves of long duration and great extent may yield to this treatment."

There appear, however, to be two discrepancies in your editorial article to which we wish to allude. In the first place we fail to understand how, in view of the three conclusions to which you had already come, the next statement can be substantiated—viz, "the demonstration was of value and interest solely as indicating the method adopted and the extent to which curves of the spine will yield to force." And in the second place in an early part of your remarks you speak of the method as "an altered form of an old and discarded treatment of Pott's disease of the spine," and later

[1] Brit. Med. Jour., Oct. 2nd, 1897

Digitized by Google

as a "new treatment." The desire to see ultimate results can and will be gratified when sufficient time has elapsed for the spines to become consolidated which in the nature of things must take at least twelve to twenty-four months. We regard our paper as a timely and not a premature communication delivered with the object of demonstrating the facts and conclusions you have described as "being clearly shown." We are, Sirs, yours faithfully,

A. H. TUBBY.

Weymouth-street, W., Nov. 27th, 1897. ROBERT JONES.

*** We fail to appreciate the "discrepancies" our correspondents allude to. Spinal curvature is not the essence of spinal caries but an accident in its course, and we are of opinion that the authors of the papers at the Clinical Society offered no material evidence to show that the treatment they described and illustrated is of value in the treatment of the disease as distinguished from the deformity with which it is often accompanied. It is not unusual to describe "an *altered* form of an old" treatment as a "new" treatment; indeed, if the word were not to be used in this sense it would have to be almost banished from modern medical literature. We shall await the demonstration of the ultimate issue of this treatment with open mind and in the meantime remind our correspondents that a demonstration of a method of treatment does not afford material for the discussion of the therapeutic value of that treatment.—ED. L.

THE INDIAN MEDICAL SERVICE.

To the Editors of THE LANCET.

SIRS,—We have now such an unsatisfactory condition of the Medical Department of the British Army that anything which tends to impair the position and diminish the efficiency of one of the allied departments will I am sure receive consideration at your hands. Hitherto the advantages offered by the Indian Medical Department to members of the profession have been sufficient to induce our best men to become competitors at the examinations, and there are always plenty of good candidates for vacancies. Perhaps this is the reason why the authorities are beginning to make encroachments on what should be regarded as rights. To many perhaps the changes made may not appear important, to those affected by the changes they are so, and appear to indicate the inauguration of a period of interference, the result of which may be to the detriment of the service, of which they are at present proud to be members. For instance, no allowance is now made to a medical officer for the expenses involved in moving his charger from one station to another when he is on duty, whilst a combatant officer receives a station warrant which enables him to take his horse without expense whether the stations are far apart or not. This sometimes presses very hardly on a junior officer. Again, when a medical officer is attached to a native regiment for duty he is not given staff pay until he has passed the lower standard examination in Hindustani, although he performs all the duties which will devolve on him after the passing of the examination. This is all the more a hardship when the medical officer is sent to serve with a regiment on the frontier, which occasionally happens, and is refused leave from his post for the examination. He may be detained for several months on duty and yet receive no consideration, whilst the newly joined wing-officer or squadron leader is granted the extra pay on joining the regiment and before passing the examination

The question of private fees and presents from native chiefs who may have been patients is one into which I will not enter now; it is a large question and demands attention from one more conversant than myself with the facts of the case. There appears, however, to be little doubt that the British Resident at the court of a native potentate occasionally exercises his power in estimating the value of the services rendered by the medical officer at a sum which is, perhaps, hardly adequate, and conveys his decision in a manner which is not only harsh but unfair, whilst the snub which the would-be donor of the gift receives must make him chafe at the presence of the official meddler. Some of the presents which have been given have been possibly more than adequate to the service rendered in the opinion of government officials and have aroused their jealousy, but it is surely ill-advised for the Government to interfere too much in what should be a private transaction between doctor and patient. The prospect of obtaining high fees must be a strong inducement to many to perfect their knowledge and gain such a reputation as to cause a demand for their services by those well able to pay.

The abolition of the two posts of Surgeon-General in Bombay and in Madras, and the appointment of a Surgeon-Colonel with the added rank of Inspector General of Hospitals cannot be regarded as a step in the right direction. The officer so appointed has to do the same kind of work as the former holder of the post—the Surgeon General—and has the same amount of responsibility, but receives only the pay which was paid him before (so-called) promotion, and when he retires is only entitled to the pension of Surgeon-Colonel and not that of the higher rank.

I do not think, Sirs, that a finer body of public servants exists than the Indian Medical Service, it is simply invaluable to the Empire of India, and its members would probably be the last to complain, however unfairly treated. There is all the more reason for those at home with the efficiency of that service at heart to raise a word of protest against procedures on the part of the Government which are sometimes unfair, sometimes ungenerous, and occasionally hurtful, to those who, bound more or less by the rules of the service, are unable to raise their own voices in protest.

I am, Sirs, yours faithfully,

London, Nov. 16th, 1897. PRŒLIUM.

"DR. MENDINI'S HYGIENIC GUIDE TO ROME."

To the Editors of THE LANCET.

SIRS,—With reference to your reviewer's remarks in THE LANCET of Oct. 9th. p. 919, about the "reckless consumption of quinine," while I admit that its use at other times than during illness will to some extent interfere with its successful use when fever comes on, does not this, however, strike at the use of the drug as a prophylactic whether so used by "medical advice" or otherwise (residents in malarious countries do not need medical advice to use quinine; most know its value)? I wonder what your reviewer would think of the gigantic experiment going on in Bengal and Punjab gaols for the past three years. From June to November for three years past every prisoner in Bengal and Punjab (32,000 in all) has been given either with lime-juice or with sulphuric acid daily for five months five, ten or fifteen grains of either quinine or cinchonidine and no bad results have been heard of. If quinine is such a deadly "poison to the vaso-motor system" as Tommasi-Crudeli says how is it so constantly recommended for prophylactic use? I have now for three years for five months each year given cinchonidine sulphate to 1200 prisoners daily and have never seen anything approaching a bad effect; a few cases (and very few) of mild headache and buzzing in the ears are the worst results I have seen and I have been on the look out for such. On the contrary the results of the prophylactic issue have been, in my opinion, exceedingly good. In my own large central gaol there has been a death-rate of only 9·0 per mille in 1895 and 7·5 in 1896, a result which few prisons with over 1200 prisoners in non-malarious England will beat, and in the present very malarious and famine year the results of the cinchonidine parade have been also very good—viz., the mildness of the cases of ague and as in the past two years the almost total absence of bowel complaints. Moreover, the Bengal Government have, in my opinion, done great good by encouraging the "reckless consumption" of quinine by selling it in "pice packets" in every post-office in every village in populous Bengal. In a malarious country like either Italy or Bengal I should be sorry to see people wait for "medical advice" to take a dose of quinine.—I am, Sirs, yours faithfully,

Buxor, India, Oct. 27th. W. J. B.

BARRY ACCIDENT HOSPITAL.—The committee of the Barry District Nursing Association and Accident Hospital held a meeting on Nov. 23rd under the presidency of Mr. G. Neale, L.R.C.P. Edin., J.P. The secretary reported that the financial difficulties were considerable and added that he thought they would have to discontinue the work if the subscriptions were not increased. It was decided to fully consider the financial position of the association at the next meeting.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Lunacy Difficulty in Lancashire.

THE unfortunate *contretemps* which resulted from the refusal of the Mill-road Infirmary authorities to admit the wandering lunatic alluded to in an annotation in the last issue of THE LANCET has given occasion to the West Derby guardians to explain their position in the matter. The chairman of the Mill-road Infirmary pointed out at the last meeting of the board that the guardians had done their utmost to stir up the Lancashire Asylums Board to make further provision for lunatics in the county asylums and on several occasions had had some sharp passages of arms with the Asylums Board. He had no hesitation in saying that the blame rested entirely with the Asylums Board. He further stated that the Commissioners in Lunacy had backed them up in refusing admittance at Mill-road to police cases; but on the other hand no one had ever been refused when accommodation could be found. Other members concurred in the censure of the Asylums Board. At the annual meeting of the Lancashire Asylums Board held at Preston last week the chairman contented himself with saying that the board were being roundly abused for not providing additional accommodation in the county asylums. A new asylum is about to be erected at Winwick for the sum of £253,000, which will be ready for the reception of patients in two and a half years! The wards for male suicidal patients at Rainhill are also to be enlarged, fourteen single rooms are also to be added to the female refractory ward, and the admission wards are also to be enlarged, the total cost of which will amount to £5900.

Health Committee: the Cost of Disinfecting Houses.

Owners of house property in Liverpool have long felt it a hardship that the cost of disinfecting their tenants' houses after the occurrence of infectious diseases should fall upon them instead of upon the tenant or municipal authority. The considerate action of the health committee will now relieve them of a portion of their liabilities. After the first of January next the work of stripping the papers off the walls of infected houses will be done by the health committee; for which purpose the sum of £1000 will be included in the estimates for the year 1898. This concession has been brought about by the action of the Land and House Owners' Association which has agitated in the matter for a considerable time.

A Nurse's Quarantine: A Wholesome Rule.

A case of interest to employers of nurses in attendance on infectious diseases recently came on for trial before Judge Shand at the Liverpool County Court. The defendant's child was suffering from scarlet fever and was nursed by the plaintiff; the latter now claimed from the defendant one week's additional wages and expenses for the period during which she remained in quarantine. The rules of the nurse's home where she was employed prohibited her from accepting another engagement until she had undergone disinfection for one week. His Honour gave judgment for the amount claimed and remarked that the rule alluded to above was a wholesome one and clearly in the interests of the public.

Ladies' Charity and Lying-in Hospital: A New Departure.

A new departure is about to take place in the conditions for the admission of patients to the Lying-in Hospital. At present none but married women on production of their "marriage lines" are admitted. A more generous and humane spirit has now infused itself into both committees (ladies' and gentlemen's). The two committees have unanimously decided that some provision should be made for unmarried women in their first confinement. It has not yet been arranged whether the accommodation for such cases shall be in the hospital or in wards outside it. Additional funds, it is needless to say, will be required to enable the committees to carry out this most kindly act of charity. All right-thinking people will congratulate the joint committee on its large-heartedness and good common sense in introducing such a long-needed reform in the economy of the hospital, which after all is only in accordance with the gospel of humanity.

Annual Dinner of the Medical Students of University College, Liverpool.

In point of numbers the medical students' annual dinner, which took place on Saturday evening last at the Adelphi Hotel, was the most successful ever held; 150 gentleman sat down to an excellent repast. The students were in great "form" and thoroughly realised their importance on the festive occasion.

Bacteriologist to the Liverpool Corporation.

Professor Rubert William Boyce, of University College, Liverpool, has been appointed analyst to the corporation at a salary of £230 per annum, which provides for 200 analyses of food, including meat, milk, &c., and 100 analyses of water. The appointment although technically that of "analyst" will be for all intents and purposes bacteriological; but as the Food and Drugs Act only makes provision for the former title the corporation have no power to appoint a bacteriologist pure and simple. With the large field for scientific observation which Professor Boyce will now have at his command the experience gained will not only be of incalculable benefit to the city of Liverpool but also to the North of England in general for which his laboratory will eventually become the bacteriological depôt. It is needless to say that Dr. Boyce's new appointment is in addition to that of his professorship in University College and will be received with approbation by his numerous friends here.

Nov. 30th

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

The Western Infirmary, Glasgow.

No progress towards the settlement of the dispute with Professor Macewen can yet be recorded. The report submitted by the managers to the annual meeting on Nov. 26th expressed the view that the proposed rearrangement of wards was quite in harmony with the agreement between the University and the infirmary. At the same time it was allowed that the Senate does not assent to this view and it was intimated that negotiations are at present proceeding which the managers trust will soon lead to an amicable settlement. It is understood that whilst there have been conferences between the managers and the university representatives no terms of agreement have been arranged. The terms of the report led to some discussion at the meeting of the subscribers and an endeavour was made both to obtain more information and to bind the managers to restore the third ward to Professor Macewen's care. Neither of these attempts was, however, successful and the proposal to substitute the name of another gentleman for one of the nominees in the official list was also fruitless. The meeting therefore resulted in a decided victory for the managers, though all the speakers agreed in their estimate of the great value of Professor Macewen's work and expressed their conviction that every effort must be made to retain his services for the University and the infirmary. Other features of interest in the managers' report are the announcement of the decision of the managers to erect a new building for the out-patient department at a cost of £25,000, the building to include also two wards for the treatment of cases of skin disease; the proposed conversion of the old laundry into wards for the accommodation of cases unsuitable for admission to the general surgical wards; and the extension of the nurses' home. The treasurer's statement showed a deficit on the year of the sum of £3135 8*s.* 2*d.*, which includes a sum of £693 0*s.* 2*d.* charged against the infirmary from the Lady Hozier Convalescent Home, this branch of the organisation not yet being self-supporting.

Glasgow Royal Infirmary.

The proposal to commemorate the sixty years of the Queen's reign by a partial rebuilding of the infirmary has not met with the full success for which the promoters hoped. For this the difference of opinion as to the wisdom of the proposal is in part responsible. The actual sum raised amounts to £74,000, whilst £100,000 was the total desired. At a recent meeting of the committee in charge of the scheme a letter was read from Sir John Muir offering suggestions for the improvement of the fund and the perfecting of the reconstruction scheme. The basis of the proposal is that in the new pavilions, each of which is to contain eight wards, any donor of £5000 shall be allowed to name a ward, whilst a gift of £250 shall confer a similar privilege in reference to an individual bed. Sir John

Digitized by Google

Muir accompanies his letter by the offer of an additional £5000 provided four other donors of a similar sum can be found. The plans of the new buildings have been prepared and it is anticipated that the building operations will be commenced in the spring of next year. During the period of reconstruction some of the present wards will necessarily be closed and temporary accommodation for patients is to be provided outside the infirmary.

Dec. 2nd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

General Medical Council: The New Crown Representative.

HER MAJESTY has been graciously pleased to nominate Dr. James Little, of Dublin, to succeed Dr. William Moore as the Crown representative of Ireland on the General Medical Council for the next five years.

A New Convalescent Home for Dublin.

A special meeting of the guardians of the South Dublin Union was held on Nov. 29th to consider the advisability of establishing a convalescent home for patients suffering from infectious diseases which would be practically an auxillary to the Hardwicke and Cork-street Fever Hospitals. A resolution was proposed that Kimmage House and lands in the neighbourhood of Terenure should be purchased for the purpose, but it met with very strong opposition on the part of the residents in that populous district. Sir Frederick Shaw read a memorial signed by many of them protesting against the injury to valuable property that would follow the adoption of the scheme suggested. It was pointed out that the Terenure College for boys and a large poor school educating about 300 children were both situated within a few hundred yards of the proposed site. After a long discussion the resolution was ultimately rejected by a large majority. The guardians are therefore baffled again in their efforts to establish the much required convalescent home. It will be remembered that a former attempt to locate the hospital at Blackrock raised a storm of very natural opposition from the residents there and from the press of Dublin as well. The public were informed on that occasion that Dr. Blyth and other eminent sanitarians had made very strong statements as to the long "striking distance" of infectious disease and the advisability of the complete and thorough isolation of hospitals containing it. It is evident that the guardians of the South Dublin Union must, next time, look further afield.

A Medical Deputy-Lieutenant.

Sir Francis Cruise, M.D., of Newtown-Cruisetown, Nobber, in the county of Meath and Merrion-square, Dublin, has been appointed a Deputy-Lieutenant for the county of Meath. Sir Francis Cruise is consulting physician to the Mater Misericordiæ Hospital.

Viceregal Visit to the Royal Hospital for Incurables, Dublin.

Her Excellency the Countess Cadogan paid a private visit to the Royal Hospital for Incurables, Morehampton-road on Nov. 29th for the purpose of inspecting the articles made by the patients for the sale of work which is about to be held there. Her Excellency made many purchases and spent a long time in the wards of the institution where she spoke kindly and graciously to many of the poor inmates, especially to those in the department for phthisical cases where, among many other interesting patients, is to be encountered a man who was orderly to General Gordon at Khartoum.

The O'Grady Memorial.

A meeting of the executive committee in furtherance of this memorial was held at 90, Stephen's-green, Dublin, on Monday evening, Nov. 29th, Sir George Duffey, M.D., in the chair. The hon. treasurers announced a considerable number of subscriptions. The committee having transacted all necessary business adjourned till Dec. 13th. Further subscriptions will be received by the hon. treasurers, Mr. M. A. Donnelly and Mr. George de Belle Ball.

The Belfast Municipal Elections.

These elections consequent on the enlarged area of the city were held on Nov. 25th and the results present two remarkable features—the success of the Labour candidates and of the members of the medical profession. The United Trades Council put forward six candidates, all of whom were successful, and in a number of the wards the Labour candidates headed the poll. Eleven medical men presented themselves as candidates for the corporation and of these six have been elected—Alderman Graham, M.D. R.U.I., Alderman Bigger, M.D. R.U.I., Councillor H. O'Neill, M.D. R.U.I., Councillor T. White, L.R.C.P., L.R.C.S. Edin., Councillor A. V. Browne, L.R.C.P., L.R.C.S. Edin., and Councillor O'Connell, M.D. R.U.I.

Letterkenny Water-supply.

At a special meeting of the Letterkenny town commissioners held on Nov. 25th it was reported that the tank at Glencar was in a most objectionable condition, half filled with a deposit of peaty matter and the spring filled up with filth and mud. The basin had never been cleaned out since 1880. It was decided to have the reservoir, drains, &c., of the present supply cleaned out, and a committee was appointed to devise means for supplying the town temporarily while these cleansing operations were being done.

Belfast Nurses' Home and Training School.

At the annual meeting held on Nov. 29th it was reported that this society was in a flourishing condition there being a balance of £251 17*s.* 4*d.* in hand. Private cases to the number of 506 had been attended to in addition to the work done in the Belfast Royal Hospital, where there are twenty-four probationers at work as well as the staff and ordinary nurses. Special reference was made to the death of the senior nurse of the hospital, Miss Hanna, who for thirty years was staff nurse in the Belfast Royal Hospital, where by her kindly manner and good-nature she secured the respect and regard of all who came in contact with her.

The Payment of Consultants by Poor-law Guardians.

A man who had been found in the street by the police in an unconscious condition was recently conveyed to the Mitchelstown Union Hospital. Mr. Walsh, the medical officer, on examination discovered a depressed fracture of the skull and instructed the master of the workhouse to summon Dr. Corby, of Cork, by telegram. Prior to Dr. Corby's arrival the patient recovered consciousness and absolutely refused to permit an operation to be performed. Dr. Corby in due course applied to the guardians for his fee, but they declined to pay it on the ground that in accordance with the terms of a circular recently issued by the Local Government Board Mr. Walsh should have called in "the nearest doctor," as it was a case of emergency. In reply Dr. Corby pointed out that the circular referred to was issued in the interests of the sick poor and that the Local Government Board could never have intended that their circular should apply in every case of emergency as otherwise such incongruities might occur as the calling in of an ophthalmic specialist to attend a midwifery case. The guardians had also before them a communication from Dr. Corby which had been addressed by him to the Local Government Board but they persisted in their determination not to pay the fee. The decision of the Local Government Board is now looked forward to with considerable interest by consultants and Poor-law medical officers generally and Dr. Corby has decided to bring the matter before the superior courts if necessary.

Dec. 1st.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Etiology of Cirrhosis in the Intemperate.

M. LANCEREAUX and M. Laborde have laid some further details of their researches into this matter before the Academy of Medicine. M. Lancereaux announced that the inquiry which was demanded to set aside their views had already been put in hand by M. Boix and M. Lestienne. He also read a letter from Dr. Viola, of Padua, which completely confirms his point of view. The Italian practitioner states that hepatic cirrhosis was unknown in the valley of the Po previously to the introduction of the wines of the South of France and those of Spain which wines are to-day all plastered. M. Laborde, on the other hand, read a letter from a medical man who has practised in Burgundy for thirty-eight years and who plainly proves that it is the alcohol in wine that must be held responsible for the occurrence of cirrhosis. He lays stress upon the fact that real Burgundy is not plastered but is over-alcoholised by the addition of sugar to the must

Digitized by Google

at the moment of fermentation. Alcohol must therefore be considered as an undoubted factor in the etiology of cirrhosis.

Bone Grafting.

At the same meeting of the Academy of Medicine M. Dubar, of Lille, read a paper upon the case of a little girl, aged ten years, in whom he had performed resection of the wrist for tuberculous disease. With the intention of giving some firmness to the resulting joint M. Dubar, after having removed the diseased bone, filled up the gap with fragments of bone taken from the femora of an eight days' old puppy. The wound was simply dressed and drained and the patient made an uneventful recovery and has good use in her hand. Her wrist is firm, painless, and moveable. In order to see what had become of the transplanted fragments an x ray photograph of the wrist was taken when it was seen that some of them were lying in the midst of newly-formed fibrous tissue and others had grown into the remnants of the carpal bones, while they had all slightly increased in volume.

Foreign Students.

At a recent meeting of the Municipal Council the Prefect of the Seine made known the decision of the Superior Council of the University as to the admission of foreign students. In his letter of Nov. 10th M. Gréard, the vice-rector, wished it to be known that foreign students would be admitted to the lectures of the various faculties of the University of Paris in accordance with the by-law of the Municipal Council passed in compliance with the proposal of M. Astier. In returning thanks to the University for its decision M. Astier said that he hoped that the measures to be taken in future would be the means of attracting foreign students to Paris.

The Causation of Pleurisy.

M. Le Damany has published the results of his researches into this subject founded on an examination of eighty cases of pleurisy of which fifty-four were first cases. From the point of view of pathology he considers that the parts played by cold or the rheumatic diathesis in the case of a first pleurisy are almost *nil*, but on the other hand one can almost always demonstrate in pleuritics the existence of a tuberculous soil. As to bacteriology M. Le Damany observed that inoculation carried out in a special manner of the exudation from fifty-five cases of pleurisy gave rise in forty-seven cases to evident tubercle in the guinea-pig, while in eight cases the results were negative. The effusion in four of these latter was bacteriologically sterile but clinically tuberculous. From these researches M. Le Damany considers that only one sero-fibrinous pleurisy is due to the invasion of the pleura by a microbe and that is tuberculous pleurisy. The other microbes which have been found in the pleural cavity produce purulent effusions.

Unjust Imprisonment of a Medical Man.

A recent proof of the animus of the magistrates against medical practitioners in France has just been afforded by the following case which has provided a second victim to succeed the unfortunate Dr. Laporte. In this instance the blow fell on Dr. Rémond, a country practitioner, settled at Villeneuve-sur-Yonne, where he was highly respected. One evening two gendarmes arrested him without any warning, took him to the railway station, put him in a prison van, and conveyed him to Paris where he remained in prison for six days without the nature of the charge being disclosed to him. At last a magistrate examined him and informed him that he was accused of having committed rape a year previously on a young woman who had given his name as being her assailant. He was further accused of having put her to sleep by means of a narcotic, under the influence of which she had robbed her father of 500 francs (£20), this money being spent in buying finery and in living extravagantly at an hotel for four days. She alleged that she had met him in the street while she was going for treatment to a hospital for nervous diseases. In vain did the unfortunate man protest that he had never seen the young woman, that she was hysterical and obviously lying, and that all the story of the narcotic was entirely false. The magistrate still kept him in prison. At last he was able to prove that on the day named by the girl he had been engaged in a consultation with a professional colleague. The girl then said that she had made a mistake in the day and the magistrate continued to believe her. After he had been in prison for forty-five days a number of witnesses gave evidence that they had met the young woman accompanied by an individual who had no resemblance to Dr. Rémond, so the magistrate was compelled to release him for want of evidence. This occurrence has caused great excitement in the medical world.

Opening of a Hospital for Incurables at Brévannes.

The authorities of the Assistance Publique are going to transfer from the Laennec Hospital to Brévannes those patients who are suitable to be taken in under the rules of the newly-founded institution. Such patients are chronic incurables, especially those suffering from phthisis and heart-disease. As no hospital for acute cases will take in these patients no place can be found for them at present except in the wards of the Laennec Hospital, which is not nearly large enough for all. The Assistance Publique came into possession of the ancient château of Brévannes in 1883 and a portion of it has been fitted up as a hospital to contain 100 beds. The administration further erected a special block containing 100 rooms for married couples. The park, extending to seventy-five acres, is admirably fitted as a site for an establishment large enough to make up for the lack of room at the Laennec Hospital and not only to receive a large number of chronic cases but to place them under hygienic conditions vastly superior to anything which they would be able to secure in Paris. Until the time at which it shall be decided to support these patients at their own homes by the aid of a system of outdoor relief they will find a refuge at Brévannes. The new buildings, which will be open in a few days, only represent a quarter of the immense establishment which the Assistance Publique proposes to found at this place. In proportion as need arises and funds are obtainable the new buildings will be erected in succession. According to the general plan which has been decided upon for some time past the whole establishment when completed will consist of sixteen blocks with plenty of room for 3200 patients.

The Accusation against a Graduate of the Faculty of Medicine.

Sentence has just been pronounced by the Superior Court of the University of Paris in the case of the Professor of Natural History, M. Heim, referred to in THE LANCET of Nov. 13th. He was accused of having taken various scientific apparatus and specimens from different laboratories. The court sat for eight days for six hours a day, M. Darboux, Professor in the Faculty of Sciences and Member of the Institute, being President. A number of witnesses gave evidence, and it was alleged that M. Heim had hidden in a case labeled with his name various objects belonging to a neighbouring laboratory—objects from which he had scratched out the name of the original owner and substituted his own. Some books bearing the authors' dedication to the rightful owners were among the spoil. M. Heim, although found guilty, was not condemned to the maximum penalty—namely, dismissal—for the court allowed the existence of extenuating circumstances—viz., kleptomania—and merely ordered him to be suspended. M. Heim, however, has sent in his resignation to the Minister.

The Association of the French Medical Syndicates.

This body has just held its annual meeting during the course of which M. Comby was elected President. Many important decisions were arrived at, among others one asking that the regulations regarding medico-legal experts should be modified and another declaring that the number of medical men existing was already in excess of that needed for the population so that it would be useless to create any new schools of medicine or faculties for that such would merely flatter the *amour propre* of sundry little towns and appeal exclusively to electoral interests.

The late Professor Tarnier.

Professor Tarnier died on Nov. 23rd from a malignant intestinal growth which had increased very rapidly of late and which gave rise upon the day of his death to profuse and fatal hæmorrhage. His end, however, was quiet and painless and there were present his old pupils Pinard, Budin, Bonnaire, and others. He had been for some time surgeon to the Maternity Hospital and Professor of Midwifery at the Faculty of Medicine of Paris; he was also a member of the Academy of Medicine and Commander of the Legion of Honour. He was without doubt the chief obstetrician in France and very many accoucheurs of to-day have been his pupils. His writings include the "Treatise on Midwifery" which has become classic and which he began in collaboration with his pupil Chantreuil, but it was finished on the

Digitized by Google

death of the latter with the assistance of his pupil Budin. He was the inventor of a traction forceps with a separate traction handle, otherwise known as the "*forceps à aiguille*." He was not a good speaker but his clinical teaching at the hospital was of the very first kind. He was the introducer of the antiseptic system into midwifery and thereby converted the old maternity hospitals, which had been hotbeds of puerperal fever, into healthy places. He was seventy years of age at the time of his death.

Nov. 30th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The New Tuberculin.

SINCE my last reference to Professor Koch's new tuberculin in THE LANCET of July 17th a great many articles on the subject have appeared in the *Deutsche Medicinische Wochenschrift*. The first of the series was a communication by Dr. Doutrelepont, Professor of Dermatology at the University of Bonn. He has treated fifteen patients suffering from lupus, of whom three suffered also from tuberculous ostitis. The injections were performed strictly according to Professor Koch's directions, but temporary elevation of the temperature nevertheless occurred in a considerable number of the cases. The injections were resumed as soon as the temperature became normal. An exceptionally marked reaction followed the use of a new bottle of the remedy received on July 2nd, a fact quite in accordance with the observations of Dr. Bussenius as mentioned in THE LANCET of July 17th; the samples of the preparation therefore seem still to differ very much in strength. The other symptoms were nearly the same as those described in my last article. With respect to the therapeutic effect of the remedy Professor Doutrelepont states that the ulcerations cicatrised and some of the swollen lymphatic glands decreased, but some of them suppurated and had to be removed by operation. The weight of the patients increased. The new remedy seems to be beneficial in lupus and is certainly much better than the old preparation. Too rapid an increase of the dose injected should be avoided as undesirable symptoms may be thereby produced.—The opinion of Dr. Leick, assistant physician to the medical clinic of Greifswald University, is quite different from that of Professor Doutrelepont. He has treated fifteen patients suffering from pulmonary tuberculosis all of whom had tubercle bacilli in the sputum. In no case did the amount of tuberculin injected reach the maximum of twenty milligrammes authorised by Professor Koch. Increased temperature and urticaria-like exanthems were observed by Dr. Leick in addition to the complications described by Dr. Bussenius and other observers. Although the majority of the patients improved during their stay in the hospital Dr. Leick is of opinion that the same effect would have been obtained without the tuberculin treatment. He states that in accordance with Professor Koch's directions only such cases were selected for treatment as were in an early stage of the disease and not yet pyrexial. The state of those patients, who naturally belonged to the poorer classes, as a rule very soon changes for the better without any specific treatment—merely by the good food and nursing and the other advantages afforded by residence in a hospital. A real improvement was obtained in two instances. One of these patients was a young man who after entering the hospital suffered from slight pyrexia, but his temperature became normal before the beginning of the treatment. When he left the hospital his weight had increased by 3½ kilos (= 7¾ lb.). Tubercle bacilli, however, continued to be found. The other patient, a woman, also showed an increase of weight, but she had been several times in the hospital already and had always become better without treatment. It it thus not certain that the new tuberculin has had any beneficial influence in these cases.—Professor Rumpf, of the General Hospital at Hamburg, has tried the old tuberculin, Maragliano's anti-tuberculous serum, and the new preparation. He says that the old tuberculin was very useful for deciding a doubtful diagnosis, that in some instances of peritoneal tuberculosis it even afforded quite satisfactory results, but that in many cases of pulmonary tuberculosis the illness was undoubtedly made worse. He also says that Maragliano's serum had no therapeutic effect at all and as it produced syncope in several instances it was now no longer used. The opinion of Professor Rumpf on the new tuberculin is as follows: (1) It produces infiltration at the place of injection without suppuration; (2) when the dose is very slowly increased the maximum amount may be reached, but fever may nevertheless occur in the course of the treatment; (3) the strength of the preparation is not the same in every instance; (4) it produces not only fever but cyanosis, giddiness, increase of the pulse, &c.; (5) It is uncertain whether immunity can be obtained by the remedy; and (6) it may be cautiously tried in the early stage of pulmonary tuberculosis provided that a reliable preparation can be manufactured.—Dr. Baudach, physician to a private sanatorium at Schömberg (Würtemberg), has obtained much better results than any of the preceding observers. The cause of this difference is probably that his patients being of a better social position than those of the general hospitals and the university hospitals could as a rule be kept longer in the sanatorium, and moreover enjoyed all the advantage of open-air treatment. They nearly all increased in weight, the physical signs in the lungs became better, and the general state of the patients, notwithstanding the above-described complications produced by the injections, was satisfactory. Dr. Baudach expresses confidence in the new method which however must be combined with the usual hygienic and dietetic treatment.—Cases of laryngeal tuberculosis have been treated with tuberculin by Dr. Herzfeld, of Berlin. Of seven cases only one showed an improvement perceptible by laryngoscopical examination. In the others the tuberculous process either remained stationary or extended to parts of the larynx which had previously been healthy. Dr. Herzfeld concludes that the usual local treatment would probably have given a better result.—A very remarkable observation is published by Dr. Müller, physician to the department of Diseases of the Ear in the Charité Hospital. A patient suffering from pulmonary tuberculosis and otitis media received injections of the new tuberculin. During the course of the treatment it was found that the affected ear not only did not improve, but the disease extended to the other ear and tubercles which eventually ulcerated were developed on the membrana tympani, perforation of the membrana being the result.—Cases of pulmonary tuberculosis and lupus are also described by Dr. Gerber, of the out-patient department of Königsberg General Hospital, who concludes that tuberculin has done good in some cases and therefore deserves a fair trial.—Dr. Kaatzer, of Hanover, has also formed a good opinion of the new remedy. In the majority of his cases of pulmonary tuberculosis the bacilli disappeared and there was a considerable increase of weight. His results are the best hitherto published.—In lupus Dr. van Hoorn, of Amsterdam, has obtained a marked improvement in a series of cases, whilst in tuberculosis of the bladder the injections were followed by pain so severe that the treatment had to be conducted very cautiously.—Dr. Petruschky, of Danzig, one of Professor Koch's pupils, has published an elaborate memoir on the selection of cases for the treatment, its technical details, and the results obtained of recent years with the old tuberculin, which he has continued to use in his practice.

It will thus be seen that there are wide divergencies of opinion among the medical men who have tried the new tuberculin. All of them agree that it sometimes produces undesirable symptoms which however have never led to any serious complication. It is further the general opinion that the manufacturers have not yet succeeded in producing a preparation of uniform strength. In lupus it has undoubtedly given good results; with respect to pulmonary tuberculosis some writers express much enthusiasm, but others almost a complete condemnation. Further experience is obviously required and the editors of the *Deutsche Medicinische Wochenschrift* in closing the series of articles on the subject remark that several years must elapse before the real value of Koch's treatment can be definitely ascertained.

Dec. 1st.

RUSSIA.

(FROM OUR OWN CORRESPONDENT.)

The Russian Red-Cross Expedition to Abyssinia.

DURING the past few years Russia has sent a considerable number of expeditions, scientific, political, and others, to Abyssinia. One of the largest of these expeditions was that

Digitized by Google

of the Red Cross Society which was sent early last year to tend the sick and wounded Abyssinians in the war against Italy. An interesting description of their experiences was recently given by M. Shtchusef, a medical student who accompanied the expedition, in a paper read before the St. Petersburg Medico-Chirurgical Society. The party followed the usual route to Abyssinia save that the Italians declined to allow them to pass through Massowah, and they were consequently obliged to pass through the French colony of Djibuti. The Somali desert took two weeks to cross. When Harrar was reached the war was already over; but a large number of patients soon came under treatment, and these included cases of leprosy, syphilis (secondary and tertiary), scabies, eye diseases, gonorrhœa, gastric catarrh, and one case of molluscum fibrosum. The Negus Menelik is described as a man of fifty-eight years of age, his face marked with the traces of small-pox, and at the time the Russians visited him he was suffering from ophthalmia. He showed much interest in medical matters and was present at several operations, including an ovariotomy. He even asked the members of the expedition if they had not brought a Roentgen apparatus with them! The inoculation of small-pox is said to have been practised in Abyssinia for the past two hundred years. Menelik, it is gravely stated, was desirous of sending a paper on this subject to the International Medical Congress through M. Mandon, a Frenchman, but for some reason he did not carry out his intention. According to M. Shtchusef the Abyssinians treat many forms of disease with iron; syphilitics are treated with some unknown herbs and also by exsudatives, hot baths, and eliminants. In the holy town of Aksum there is said to be preserved a book on the treatment of diseases which has been in existence for 2000 years. The Abyssinians are almost of European type in their features but their skins are black. They are monogamists; with them the religious form of marriage does not admit of divorce and consequently civil marriages are common. Justice is administered in public and punishments are awarded on the principle of an eye for an eye. For example, a man who had murdered another with a sword would be executed by the sword. For less grave crimes—as, for example, theft—the punishment may be the loss of the left hand or the right foot. M. Shtchusef, since reading the paper, has again started for Abyssinia, where he is now attached to the Russian Embassy. On the eve of his departure he read another paper before the Russian National Health Society on the Climate and Balneology of Abyssinia. Near Harrar, he stated, are a number of hot mineral springs, occupying the craters of extinct volcanoes. These springs have no little reputation among the natives for their medicinal powers. Particularly efficacious is the hot spring of Alisa-Babi. The reader of the paper was requested by the society to make further observations upon these springs on his return to the country and also to make inquiries as to the prevalence of malarial fevers and the local modes of treating them.

General News.

The museum of anatomy and surgery recently built to the memory of Pirogoff and to be called the Pirogoff Museum was opened in St. Petersburg on Sunday, Oct. 26th (old style). The total funds collected for the purpose were 115 000 roubles and the building has cost 85,000 roubles (about £9000). The opening ceremony was attended by the Prince and Princess of Oldenburg and a large number of other distinguished guests.—One of the worst inundations of recent years visited St. Petersburg on Nov. 4th (16th). A violent gale from the south-west, accompanied by snow and frost, heaped up the water at the mouth of the Neva to a height of 8½ ft. above the average. The result was that the greater part of the city was for some hours deeply under water. The facts that a large number of the poorer classes in St. Petersburg live in cellars and basements and that the inundation occurred when the thermometer was some 7° F. below the freezing point, so that there will be no possibility of thoroughly drying such habitations before next summer, combine to make the calamity a very serious one for a large section of the community.

St. Petersburg.

MEASLES AT EXMOUTH. — The elementary schools at Exmouth have been closed owing to an outbreak of measles.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

The New York Quarantine.

DURING 1896, 252,350 steerage passengers were examined at this station and out of 12,127 vessels which arrived at the principal ports of the United States during the same year (1896) 6241 or more than one half of the entire number were inspected at the New York Quarantine Station. The work of 1897 will show about the same result. During this period plague, cholera, small-pox, yellow fever, and typhus fever have existed in numerous ports throughout the world which have been in constant communication with New York, and although numerous cases of small-pox and yellow fever have reached this harbour no infection has passed the station. This fact will be appreciated when it is remembered that during certain portions of last year, and also of this, from 200 to 300 cases of yellow fever and an equal number of cases of small-pox daily existed in the city of Havana. As this place is about three and a half days' journey by water from New York it is within the period of incubation of both diseases. In order that passengers arriving from Havana and other ports of the north side of Cuba shall not be a menace to the health of this country and at the same time that commerce should not be unnecessarily interfered with it is required that all persons coming from Havana shall be supplied with a certificate to the effect that they have had yellow fever or are natives of Cuba. In either case these persons are rarely subject to this disease and can be safely allowed to pass quarantine. Persons who do not present these certificates on their arrival are removed to Hoffman Island, there to remain until the difference in time between the period occupied by the passage and five days (the period of incubation of yellow fever) has elapsed. A number of persons thus held have developed yellow fever and have been transferred to the hospital at Swinburne Island. All vessels arriving from Cuban ports are subjected to disinfection. Their crews are not held for observation as these persons are not allowed to leave the vessels which are not docked but remain in the stream where they are loaded and unloaded.

Midsummer Day Schools.

The New York Association for Improving the Condition of the Poor have undertaken an experiment of vacation instruction by providing a six weeks' midsummer term for the children who loiter in the heated streets of New York while the public schools are closed. The Board of Education when the project was first presented promptly agreed to coöperate by donating four public school buildings in crowded and destitute districts and lent such other aid as was in their power. A corps of teachers under a superintendent was organised and has worked faithfully and well. The teaching has been wholly of the manual training and kindergarten order and it is hoped that it may prove to be an object lesson so encouraging as to win wider adaptation in the ordinary curriculum of the common winter schools. A children's playground with the novelty of a sand garden was opened; it was given over to the use of boys in the morning and to the girls in the afternoon and some 200 of them romped there every day. In one vacation school about 400 boys and girls were taught kindergartening, paper folding, drawing, clay modelling, and sewing, with elementary industrial work for older boys. The hours at all the schools were from nine to twelve. By this means 1000 children have been cared for and kept off the streets during the hot summer months, which means a new life to the children of poor working people.

The New York Zoological Park.

The preliminary plans of the New York Zoological Park, to be located in South Bronx Park, one of the new acquisitions of Greater New York, have been completed and work upon them will soon be commenced. These plans include those for the lion house, monkey house, elephant house, bird house, winter house for birds, reptile house, tropical ruminants house, main restaurant, and administration buildings. Among the secondary structures there will be a flying cage, eagle and vulture aviary, buffalo house, deer barns, wolf and fox dens, bear dens, sea-lion pond, pheasant aviary, mountain sheep shelter, and duck aviaries. Particular attention has been given in connexion with this

Digitized by Google

park to as complete a system of sewerage and water-supply as science and money can create. The different houses and the outer grounds will be kept in almost as aseptic condition as the wards of a well-regulated hospital.

Lodge Medical Officers not allowed in Quebec.

The College of Physicians and Surgeons of the Province of Quebec which has the power to revoke all licences to practise medicine or surgery in the province recently passed the following resolution: "In view of the extent to which the members of the medical profession are defrauded of proper remuneration for professional services owing to the acceptance by many of positions as medical officers to various benefit societies, lodges, &c., where remuneration is arranged for by contract, it be considered beneath the dignity of our profession to accept and hold such positions. In order that all professional services shall be awarded remuneration not less than the tariff adopted by this board it is hereby enacted that members of the College of Physicians and Surgeons of the Province of Quebec shall be prohibited from accepting or retaining the position of lodge medical officer where a stipulated amount is paid annually or otherwise for professional services amounting to less than the minimum tariff adopted by this board or from attendance upon families, groups of families, or other associations at contract prices which name a stated sum for a certain term—usually an annual fee—and that no physician shall be permitted to retain membership in this College or practise in this Province who accepts such positions."

Nov. 19th.

Obituary.

HENRY WILLIAM FREEMAN, F.R.C.S. IREL., L.R.C.P. LOND., J.P.

MR. H. W. FREEMAN died at his residence, the Circus, Bath, on Nov. 28th, at the age of fifty-five years. He was born at Westward Ho, Devon, in 1842, and after education at the Bideford Grammar School went to the Middlesex Hospital, London, where he studied with marked success, taking prizes and holding resident appointments. He qualified M.R.C.S. Eng. and L.S.A. in 1864, taking the L.R.C.P. Lond. the year following and the F.R.C.S. Irel. in 1882. In 1864 he was appointed resident medical officer to the Royal United Hospital, Bath, and about a year afterwards commenced practice in that city; later he was appointed honorary surgeon to the hospital and in a few years became one of the best known of the Bath surgeons. In 1887 he was elected on the town council and the following year was appointed mayor; this office he held most successfully and at its expiration Mr. Freeman was made an alderman. In 1893 he was placed on the Commission of the Peace for the city and also for the county of Somerset. Mr. Freeman had for many years done his utmost to develop the baths of Bath and more recently had introduced the Nauheim system. When the new Queen's Baths were opened by the Duchess of Albany in 1888 Mr. Freeman presented a beautiful statue, "The Angel at the Pool"; this now stands over the fountain in the pump-room. In 1887 he offered Hamilton House, on Lansdown, as a convalescent home for the city, but the necessary funds for endowing it not being subscribed the scheme fell through. Mr. Freeman's principal work in addition to several surgical papers was "The Thermal Baths of Bath" (1888) and only last month he published a smaller work entitled "New Methods of Cure at Bath." Mr. Freeman was owner of an extensive thoroughbred stud at Weston. His health had been weak for some time, but his fatal illness commenced soon after the opening of the new pump-room in October. He leaves a widow with whom great sympathy is felt. Mr. Freeman will be much regretted and missed in Bath and his death will cause a blank in the city which it will be impossible to fill.

WATER-SUPPLY OF SHANKLIN, ISLE OF WIGHT.—At a meeting of the Shanklin district council held on Nov. 19th it was resolved that a deputation wait on the Local Government Board to urge them to give their decision on the scheme for obtaining water from Wroxall, which is about two miles distant from Shanklin.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

THURSDAY, NOV. 25TH.

THE Council met again to-day, Sir WILLIAM TURNER being in the chair, and resumed the work of the session.

The Resignation of Dr. W. Moore.

The CHAIRMAN said the President wished him to read the following letter:—

Privy Council Office, Whitehall,
Nov. 24th, 1897.

SIR,—I am directed by the Lord President of the Council to acknowledge the receipt of your letter of the 24th inst. stating that Dr. William Moore, one of the Crown Nominees in the General Medical Council, has resigned his seat in that Council.

I am, Sir, your obedient servant,
J. H. HARRISON.

Sir Richard Quain, Bart., M.D., 67, Harley-street, W.

On the motion of the CHAIRMAN the letter was entered on the minutes.

The Case of George Hamilton Wyse.

After sitting for fully an hour in private to receive a recommendation from the Penal Cases Committee the Council proceeded to the consideration of the case of George Hamilton Wyse, of 51, Talbot-street, Southport, Lancashire, registered in Ireland, June 27th, 1871, as Lic. Apoth. Hall. Dubl. 1871; Lic. R. Coll. Phys. Edin. 1871; Lic. R. Coll. Surg. Edin. 1871, who had been summoned to answer the following charges on the complaints of the Medical Defence Union and the Wigan Medical Guild:—

(1) The complaint relates firstly to a medical practice carried on under his name at 88, Adelphi-street, Preston, in the county of Lancaster, and secondly to a medical practice carried on under his name at 95, Wallgate, Wigan, in the same county.

(2) The charge against him in respect of the practice at 88, Adelphi-street, Preston, is that he covers an unqualified person named George Wyse, who is, or purports to act as, his assistant, and whom he permits and enables, under cover of his presence, name, and qualifications, to attend on and administer medical relief to patients and give medical relief to patients and give medical certificates and generally to carry on at the said place a medical practice as if he (George Wyse) were a duly qualified and registered practitioner.

(3) The charge against him in respect of the medical practice at 95, Wallgate, Wigan, is that he covers an unqualified person named Cowan, whom he permits and enables, under cover of his name and qualifications, to attend on and administer medical relief and treatment to patients and give medical certificates, and generally to carry on at the said place a medical practice as if he (Cowan) were a duly qualified and registered practitioner.

(4) The complainants are in the matter of the covering of George Wyse the Medical Defence Union, Limited; and in the matter of the covering of Cowan the Wigan Medical Guild.

Mr. R. B. D. Acland appeared as counsel for Mr. Wyse and Dr. Bateman for the complainants.

Dr. BATEMAN, in opening the case for the complainants, said that there was no dispute as to the facts.

Mr. ACLAND, interposing, said it would be necessary to call Mr. Wyse and his son to dispute the most serious allegations in the charge made against Mr. Wyse. The reason why a declaration had been made without disputing the facts alleged was that Mr Wyse had not the slightest suspicion until he received various letters that any charge had been made against him. When he first realised that there really was a charge he wrote to his Lancashire professional colleagues to withdraw it, but he was informed, in reply, that the matter was before the General Medical Council. On learning this he placed himself in communication with his solicitor, who wrote to the Council asking for an adjournment of the case, but that had been refused, and thereupon, without really understanding the gravamen of the charge, the declaration was drawn up in the form in which it was now put before the Council.

The CHAIRMAN informed Mr. Acland that he would have full opportunity to call Mr. Wyse and his son for examination.

Dr. BATEMAN thereupon proceeded with his opening of the case. He read a series of affidavits upon which he relied as proving the charges brought by the Medical Defence Union. He stated that he had no documentary evidence from the Wigan Medical Guild.

Mr. MUIR MACKENZIE thereupon read one of several documents received from the Guild in question, but as copies of the rest had not been furnished to the accused all except the one read were withdrawn.

Digitized by Google

Mr. WYSE went into the witness-box and in reply to Mr. ACLAND said he had been in practice for twenty-five years and during a little over four years had carried on his present practice at Wigan. He emphatically denied that he acted as cover to Cowan. He lived at Southport, but it could not be said that he practised there because he had seen months pass without any patients calling on him. In September, 1896, he opened a surgery at Preston and in the second week of February of the present year he closed it. The first time he heard of any complaint being made against him was last month when he received a letter from the solicitor of the General Medical Council. Before that he had heard not a word of complaint either in connexion with the practice at Wigan or that at Preston. His son lived with him at Southport and went to Preston with him every day the surgery in the town was open, which meant about four days a week. His instructions to his son were to see if any patients were waiting and if so to detain them until he came and not to sign any certificates. Shown two certificates he admitted the one was in the handwriting of his son, who apparently had acted contrary to his instructions on this particular occasion.

Cross-examined by Dr. BATEMAN witness said that his son was a student in his fifth year of study, while Cowan was not exactly a student; he was about thirty-six years of age and had studied in Dublin.

Mr. WYSE, Jun., also gave evidence. He explained the nature of the instructions given him by his father with regard to the practice at Preston and admitted that he had done wrong in signing the certificate in question.

Mr. ACLAND, addressing the Council on behalf of Mr. Wyse, complained of the manner in which the charges had been prosecuted and especially of the absence of notice to his client. Not one hint of malpractice was given to Mr. Wyse during the whole of the time that the surgery at Preston was open, and it was only on Oct. 29th of the present year when he received the communication from the solicitor of the General Medical Council that he heard of the proceedings which had been taken. In connexion with the Wigan charge only one case was brought up and the case resolved itself into whether they were to believe Mr. Wyse or the woman who had sworn the affidavit.

The Council then deliberated in private on the case.

The CHAIRMAN thereafter addressed Mr. Wyse as follows: I have to inform you that the Council having, as you know, gone very carefully into the case have come to the conclusion that the charges made against you have been proved to the satisfaction of the Council—that is to say, that you have acted as a cover, but the Council have not gone so far as to say that you have been guilty of infamous conduct in a professional respect; they have not pronounced that yet. And they have instructed me to say to you that the further consideration of the charges made against you is adjourned until the next session, which will probably be held in the month of May, when they expect you will be able to come and show them that such a charge as has been made against you can no longer be made—namely, that you have given up all such practice. The Council wish you to understand clearly that they regard this question of covering as a charge of a most serious kind against a professional man and they hope you will take the matter seriously to heart and that you will be able to report in May that no such charge can in the future be brought against you.

The Council then adjourned.

FRIDAY, NOV. 26TH.

The Council resumed work to-day, Sir WILLIAM TURNER being in the chair.

The Case of E. E. Hooper.

The REGISTRAR reported that since the meeting of the General Medical Council in May last information had been received of the death of Mr. E. E. Hooper, the further consideration of whose case was adjourned to the present session of the Council.

The Case of William John Patterson.

The Council proceeded to the consideration of the case of William John Patterson, of 33, Rodney-road, London, S.E., registered in Ireland August 27th, 1890, as Lic., Lic. Midwif. 1890, R. Coll. Surg. Irel.; Lic. Apoth. Hall, Dubl., 1890, who had been summoned to appear before the Council on conviction for the following misdemeanour:—

That he, on the 31st May, in the year of our Lord, 1897, at Brentford, in the County of Middlesex, unlawfully and indecently assaulted Fanny Amelia Ker.

The following is a copy of the certificate of conviction that had been received:—

Middlesex } These are to certify that at the Midsummer Quarter
to wit. } Sessions of the Peace, holden at Guildhall, Westminster, for the County of Middlesex, on Saturday the 3rd day of July in the year of our Lord 1897, William John Patterson was in due form of law tried and convicted on a certain indictment against him, for that he on the 31st day of May in the year of our Lord 1897, at Brentford in the said county, unlawfully and indecently did assault Fanny Amelia Ker, against the form of the statute, &c. And the said William John Patterson was thereupon ordered to be imprisoned and kept to hard labour in Her Majesty's prison at Wormwood Scrubbs for the space of nine calendar months. And these are further to certify that the record of the said conviction is still unreversed and of full force and effect. Given under my hand at the Guildhall, Westminster, this 27th day of July in the year of our Lord 1897. RICHD. NICHOLSON.
Clerk of the Peace for the said County of Middlesex.
County of Middlesex, Guildhall, Westminster.

Mr. FARRER said that although there was no appearance Mr. Patterson had put in a defence. He should like, however, to point out that this Council could not go behind the conviction which they must assume to have been lawfully and properly obtained. Mr. Patterson had written a letter on Oct. 30th, 1897, in reply to the summons, the principal point of the letter being an earnest appeal to postpone the case until he could be heard by the Council after his liberation from prison. Mr. Patterson insisted that he had done nothing more than kiss the girl and that this act was the result of some unaccountable and sudden impulse.

Mr. MUIR MACKENZIE said that the duty of the Council was imperative. In only one case—and there special circumstances arose—had they left a man upon the Register who had been convicted.

The Council decided to instruct the Registrar to erase the name of Mr. Patterson from the Medical Register.

The Case of Charles Day.

The next business was the consideration of the case of Charles Day, of 1, Benwell-road, Drayton-park, N., registered in England Jan. 1st, 1859, as Mem. R. Coll. Surg. Eng. 1841; Lic. Soc. Apoth. Lond. 1846, who had been summoned to appear before the Council to answer the following charge on the complaint of the Medical Defence Union:—

That he had acted and acts as cover to an unqualified person named Alfred Henry Day, who, acting or purporting to act as his assistant, was and is permitted, authorised, and enabled by him to carry on medical practice and administer medical treatment to and sign certificates for patients as if he (Alfred Henry Day) were a duly qualified and registered practitioner.

The complainants were the Medical Defence Union, Limited.

Dr. BATEMAN said he wished to explain how the Medical Defence Union appeared in this case. About August certain newspaper cuttings were sent to the Union with reference to an inquest upon the body of a child called O'Sullivan and to certain proceedings taken by the Registrar-General in a police-court against an unqualified man for issuing a certificate. These were forwarded to this Council to take whatever steps were thought proper.

Mr. CHARLES TOWNLEY, Superintendent Registrar of St. Mary's district, Islington, examined by Dr. BATEMAN, gave an account of the inquest and what transpired at it. The mother of the child, he said, gave evidence to the effect that Mr. Day's son attended the child, saw it several times and treated it, and after the death she was handed a certificate signed "Charles Day" although at the time Mr. Day, sen., was out of town on holiday. The District Registrar refused to accept the certificate, the coroner was communicated with, and on the instruction of the Registrar-General proceedings were taken in the police-court against the son who was fined £10 and £1 13*s.* 6*d.* costs. The coroner said that there was no fault to find with the treatment of the child by the son.

Mr. MUIR MACKENZIE read Mr. Day's written defence. His son, he said, had been his assistant for many years. He had really been his pupil, his hospital course having been interrupted. Having lost his wife and being in ill-health he (Mr. Day) left home for two days giving his son instructions to send to a neighbouring registered practitioner if any serious matters arose in his absence requiring special treatment. He gave his son instructions how to treat this particular child. On the second day of his absence the child succumbed and his son thinking that the case had been practically attended by him signed the certificate in his father's name. They both deplored what had occurred, but he was bound to say in his own defence that his son had

Digitized by Google

acted without his consent and against his instructions. He could not understand how the employment of an unqualified assistant residing in his own house and under his own direct supervision and control could be construed as an infringement of the Act and to support his view he quoted the notice given in THE LANCET in the column where unqualified assistants were advertised. This notice, he said, represented the feeling generally entertained by the medical profession on the subject. As to his son he had already suffered for the error he had committed.

Mr. DAY then addressed the Council, submitting that he had conducted his practice with all possible care.

After the Council had deliberated in private for a time,

The CHAIRMAN intimated to Mr. Day that they had come to the conclusion that the charge made against him had not been proved to their satisfaction. But the Council wished him to state that the difficulty into which he had been put had been owing to the employment of an unqualified assistant and to the opportunity which had been given to the unqualified assistant to transgress the law—that was to say, to sign a death certificate, which he had no right to do. Consequently in his further practice he would have to be very careful indeed how he carried on his work with the aid of an unqualified assistant, supposing he continued to employ one.

The Case of William Robert Nuttall Maloney.

The next business was the consideration of the case of William Robert Nuttall Maloney, of Roden-street, West Melbourne, in the Colony of Victoria, registered in England March 3rd, 1886, as Lic. Soc. Apoth. Lond. 1885, who had been summoned to appear before the Council to answer the following charges as formulated by the Council's solicitor:—

The matters charged against Mr. Maloney relate to public advertisements by him in Calcutta, Melbourne, and Belfast, and also to his conduct in associating himself with a so-called medical electrician, and in practising and conducting in public a medical electrical treatment; and it is complained against him that he seeks to attract patients by a system of extensive public advertisements of his name and address and qualifications, and of the said treatment as practised by him, in and by which persons in need of medical aid were invited to consult him professionally and adopt the said treatment, and that the advertisements systematically published by him were of themselves of a character discreditable to a professional man.

Mr. FARRER said that Mr. Maloney had been summoned and in reply had sent certain letters of defence. The matter had been brought to the notice of the Council by the Royal College of Surgeons of England, who had removed Mr. Maloney's name from their list of Members. He submitted to the Council specimens of the advertisements as well as a newspaper account of a meeting held in the Ulster Hall, Belfast. In one of his letters Mr. Maloney suggested that he had been sufficiently punished by being deprived of his place in the Membership of the Royal College of Surgeons of England. As to the electrician with whom he had been associated for a time he had fled the country when his antecedents became known. Mr. Maloney further said that his qualifications had been inserted in no advertisement with his knowledge. He explained his non-appearance before the Council with the statement that he was standing for re-election as a member of the Legislative Assembly of the Colony of Victoria.

Mr. BRYANT gave some account of the experiences of the Royal College of Surgeons of England with Mr. Maloney.

The Council found the charge proved and adjudged Mr. Maloney to have been guilty of infamous conduct in a professional respect and directed the Registrar to erase his name from the Medical Register.

The Case of William Masson.

The Council proceeded to the consideration of the case of William Masson, of Cottingham, East Riding of Yorkshire, registered in Scotland, December 12th, 1888, as M.B., Mast. Surg. 1888, Univ. Aberd., who had been summoned to appear to answer the following charge on the complaint of Mr. Edward Ball, of Southport, registered as Lic. R. Coll. Phys. Edin. 1886; Lic R. Coll. Surg. Edin. 1886; Lic. Fac. Phys. Surg. Glasg 1886, viz.:—

That he had acted and acts as cover to an unqualified person named George Watson, who, acting and purporting to act as his unqualified assistant, was and is permitted, authorised, and enabled by him to carry on medical practice and administer treatment to patients as if he (Watson) were a duly qualified and registered practitioner. It is particularly alleged against him (Masson) that George Watson attended a woman named Higgins in her confinement, using instruments upon her, and that on the death of the woman he (Masson) signed and gave a death certificate purporting to certify that the woman had died of eclampsia.

Mr. Farrer, the Council's solicitor, attended to advise the Council on the case, and Mr. Muir Mackenzie was present as legal assessor. Dr. Masson, the accused, appeared in response to the summons along with his counsel, Mr. J. Scott-Fox, instructed by Mr. George Trenam, solicitor.

Mr. FARRAR stated that Mr. Ball, the complainant, did not attend. He had sent a letter which intimated that he did not intend to be present at the investigation; he had supplied information which he had received from the friends of the deceased and he did not see what use he could be.

Dr. BATTY TUKE wished to know who, then, was the prosecutor in the case.

The CHAIRMAN replied that the case had been before the Penal Cases Committee and inquiry had been ordered.

Mr. MUIR MACKENZIE read the documents in the case. These included a first letter, dated Aug. 2nd last, and a further letter in support of the charge, enclosed with the latter being answers to a series of questions, some of them drawn up by the President of the Council and also extracts from a letter addressed to a certain "Dear Fred" by the deceased's husband.

Dr. GAIRDNER said that in this letter of Mr. Ball they had two or three very grave assertions of which, so far as appeared, they, in the absence of the complainant and witnesses for him, would have no proof whatever.

Mr. SCOTT-FOX submitted that in the circumstances the natural course that ought to be adopted was to dismiss the case without a moment's consideration. That would be the course adopted in any regularly constituted court of justice. However, as the Council wished inquiry he would proceed and Dr. Masson who was present would answer any questions addressed to him. Pointing out that Mr. Ball's letter to the Council contained the sentence, "I wish to keep my name silent in the matter," he said he thought that threw some light on a case for the accusations raised in which there was no evidence whatever. The indictment was unfair; it was absolutely unjustified. There was no denial on the part of his client that George Watson was unqualified, but Watson had acted during some twenty years as assistant to his late father, Dr. Samuel Watson, to Mr. Chambers, who succeeded the latter, and to Mr. Baldwin, who followed Mr. Chambers. He had had great experience and had attended down to the present perhaps as many as 2000 cases of childbirth. He did not assume the title of "doctor" and there was no name-plate on his door or anything to show that he practised on his own account, which he did not. Counsel read Dr. Masson's written explanation in answer to the charge. This showed that he had purchased the practice in 1893 from Mr. Baldwin for £750. He continued Mr. Watson as assistant, but he had never heard it suggested that he was other than an unqualified assistant. Dr. Masson had never asked Mr. Watson to take upon himself and assume or perform any duty which was outside of duty that could be performed by unqualified assistants. Though he lived in the house occupied by his late father there was no surgery there and not during Dr. Masson's connexion with Cottingham had there been complaint or suggestion of complaint made to him as to Mr. Watson, who had not and never had had any pecuniary interest in Dr. Masson's practice. The summons to appear before the Council was the first intimation Dr. Masson had that any explanation was required in the case of Mrs. Higgins. Her relatives had made no complaint before they left the district. Counsel concluded by asking the complaint to be dismissed with the contemp which it merited.

In answer to members of the Council Dr. Masson stated that he had seen the woman three times before her death and the certificate he gave stated the true cause of death. He admitted that Watson had told him that he used forceps. He had no authority to use instruments. It was in violation of his instructions that he did. They were not accused's instruments but had belonged to Watson's father. It was untrue that the accused was dominated by the local influence of Watson and it was decidedly untrue to say that Watson had the whole practice of the place in his hands. Under the agreement he (Dr. Masson) obtained on taking over the practice he could dismiss Watson at three months' notice and he could restrict him from assisting any other practitioner in the district.

In answer to Mr. SCOTT FOX, Dr. Masson said that Mr. Watson never took cases for his own profit and any fees received by him were always handed over to accused.

The case having been closed the Council deliberated in private. On the re-admission of the public

Digitized by Google

The CHAIRMAN, addressing Dr. Masson, said he was instructed to tell him that the charge made against him had been proved to the satisfaction of the Council, but the Council were not prepared at this time to judge him guilty of infamous conduct in a professional respect. They, however, would further consider the charge during their next session which would be held in May, 1898. He thought Dr. Masson would understand from what had happened that he would have to reconsider his position as to the employment of this unqualified assistant.

Dr. MASSON: He is now dismissed.

The CHAIRMAN: Oh, he is now dismissed. Very well, the further consideration of the charge is adjourned till May next when you will be asked to appear before the Council.

The Council adjourned.

SATURDAY, NOV. 27TH.

The Council resumed work to-day, Sir WILLIAM TURNER being again in the chair.

Nomination of Dr. James Little.

The REGISTRAR read a letter from the Privy Council announcing that Her Majesty in Council had nominated Dr. James Little to be for five years a member of the Council for Ireland in place of Dr. William Moore, resigned.

The Case of Julius Mostertz.

The Council proceeded to the consideration of the case of Julius Mostertz, of 13, Salisbury-road, Noel-park, N., registered in England as Lic. Soc. Apoth. Lond. 1893, who had been summoned to appear before the Council to answer the following charges on the complaint of the Medical Defence Union, Limited:—

1. The complaint relates to a dispensary or establishment carried on or conducted at 13, Salisbury-road, Hornsey, under the name of the Noel-park Dispensary.
2. The complaint is that Mr. Mostertz, being a registered medical practitioner, acts as cover to an unqualified person named George W. Johnson, who, purporting to act as his assistant, carries on at the said Noel-park Dispensary a medical practice, and who, under cover of Mostertz's name, presence, and assistance, is enabled to and does attend on and administer medical treatment to patients and carry on such medical practice as though he were a duly qualified and registered medical practitioner.
3. The complainants are the Medical Defence Union, Limited.

Dr. Bateman, with Mr. Hempson, solicitor of the Medical Defence Union, appeared for the complainants and Mr. Ward appeared for Mr. Mostertz.

Dr. BATEMAN, opening the case, said that some years ago a Mr. Johnson, M.R.V.S., opened at 13, Salisbury-road, Wood-green, a chemist's shop under the style of the Noel-park Pharmacy, Mr. Johnson being a registered chemist as well as a veterinary surgeon. This Mr. Johnson died and the pharmacy was carried on by the widow with the assistance of a man known as Mr. George W. Johnson. Some little time ago the medical men and others in the district began to hear very frequently of a "Dr. Johnson" engaged in practice, and finding that there was a certain amount of unqualified practice going on and being determined to put a stop to it the medical men called a meeting by post-card. The meeting was to be at Mr. Tomlin's house and the post-card set forth that its purpose was to consider what steps should be taken to cause the unqualified practice to cease. The post-cards were sent to all the medical men in the district whose names could be remembered, and among the rest to Mr. Mostertz at his residence in Lordship-lane. Next morning Mr. Tomlin received a letter signed by "G. W. Johnson." The letter started with an extract from the notice as to unqualified assistants appearing in the advertisement columns of THE LANCET and then went on to say that the writer courted the fullest investigation as to whether he had infringed the regulations of the General Medical Council. He admitted having prescribed for hundreds of people since he had resided in Wood-green, but when he had been asked to visit he had told them that he could not do so as he had not quite finished his curriculum, but that the doctor to whom the dispensary belonged would call upon them and could easily do so because he lived only a hundred yards away. At the meeting, which was attended by a large number of medical men, Mr. Mostertz after a time got up and said that he had handed his post-card to this Mr. Johnson. The meeting passed a resolution to the effect that unless Mr. Mostertz severed his connexion immediately with Mr. Johnson, either by withdrawing absolutely from Noel-park Dispensary or dispensing with the services of Mr. Johnson, the matter would be reported to the General Medical Council. Later a letter was received from Mr. Mostertz saying that he could not allow any practitioner or combination of practitioners to dictate to him how he was to conduct his dispensary so long as he had not been guilty of unprofessional conduct and further that when Mr. Johnson left as he intended to leave for Australia he (Mr. Mostertz) would not hesitate to engage another unqualified assistant. Another meeting was held at which it was decided that the matter should be laid before the Medical Defence Union in order that proceedings might be taken before the General Medical Council. There were declarations by Thomas William Tyrrell and Albert Bright. The former said that he called at the dispensary and saw Mr. Johnson, who felt his pulse and looked at his tongue and said he was suffering from gastric catarrh and indigestion and would give him a medicine. Mr. Tyrrell said he saw Mr. Johnson make up the medicine and he handed it to him and gave him directions as to its use. The charge was 7*d.* and when Mr. Tyrrell remarked that it was very cheap Mr. Johnson replied that he could not charge west-end prices in Wood-green. Mr. Tyrrell also described an interview with Mr. Mostertz and told how on another occasion he went to the dispensary and saw certain certificates and qualifications with regard to Mr. Mostertz displayed. The declaration of Mr. Albert Bright had reference to a visit paid by him to the dispensary.

Mr. THOMAS WILLIAM TYRRELL was then called as a witness and in reply to Dr. BATEMAN said he was a clerk residing in East Dulwich and was instructed by Mr. Hempson, solicitor of the Medical Defence Union, to visit the Noel-park Dispensary.

Cross-examined by Mr. WARD witness denied that he gave a wrong address.

By Dr. BATTY TUKE: He was in the employment of Mr. Hempson as a clerk.

Dr. A. CAMPBELL, examined by Dr. BATEMAN, said he called at the dispensary and asking for the doctor saw Mr. Johnson. Witness was examined by Mr. Johnson, who prescribed for him and charged him 6*d.* for medicine and advice.

Dr. BATTY TUKE: Why did you go there?

WITNESS: Curiosity pure and simple.

Dr. BATTY TUKE: Were you ill?

WITNESS: No, I was not ill. I said I had a cold.

Dr. BATTY TUKE: How did your evidence come here?

WITNESS: Because I live in the neighbourhood.

Dr. BATTY TUKE: How did it come under the observation of the Medical Defence Union?

WITNESS: I let all the doctors in the place know I had been there as a joke.

Dr. BATTY TUKE: Were you paid for going?

WITNESS: No; it was I who paid.

Mr. BRUDENELL CARTER: May I ask you if you took the medicine?

WITNESS: No, sir; I was asked if I would take a dose there and then but I said I would wait until I got home.

Mr. R. F. TOMLIN was the next witness and in answer to Dr. BATEMAN said he lived in Wood-green, not far from Mr. Mostertz and it was he who called the meeting.

Cross-examined by Mr. WARD: He had never complained that Mr. Mostertz called himself Dr. Mostertz. He invited Mr. Mostertz to his house along with the other medical men of the district and he remembered that as Mr. Mostertz left the house he asked him to give up this class of practice and make himself agreeable and join in with the rest of the medical men.

Dr. R. E. FOOTT, one of the medical men who attended the meeting, also gave evidence.

Dr. BATEMAN then intimated that this closed the case for the complainants.

Mr. WARD, addressing the Council on Mr. Mostertz's behalf, said the question to decide was whether or not Mr. Johnson was practising in this place under cover of Mr. Mostertz. He proposed to call Mrs. Johnson, who would tell the Council that since the death of her husband in May last she had carried on the pharmacy which she had a perfect right to do under the Pharmacy Act as the widow of a qualified man. By a fortunate accident Mr. Alfred William Johnson came to stay there while his brother was ill. During the illness he looked after the shop and after the death he assisted the widow in the business. In August last Mr. Mostertz went to Mrs. Johnson and engaged at a weekly rent of 10*s.* the room which he now used as his dispensary. Mrs. Johnson was the tenant of the house and paid the rent and taxes for it. Mr. Mostertz employed

Digitized by Google

Mr. Johnson at a salary of £1 per week, but never with the permission of Mr. Mostertz had Mr. Johnson practised. Mr. Mostertz had been careful to see all the patients himself and he left word with Mr. Johnson to call for him if any person came after dispensary hours. If Mr. Johnson did what Dr. Campbell had stated then he had exceeded his instructions and he submitted that the Council should not visit upon Mr. Mostertz the fault or offence of his assistant. In his deposition Mr. Mostertz said that so far as he knew there was no such person as "George W. Johnson" in existence. He employed Alfred William Johnson as a dispenser and paid him £1 a week for his work in that capacity and for keeping his books and announcing patients. When he saw Tyrrell he told him that Johnson was his unqualified assistant acting under his supervision as he (Johnson) had acted for twenty-three years to eight other registered practitioners in different parts of the country.

Mr. MOSTERTZ then went into the witness-box. He denied that he acted as cover to Johnson in any way. He simply dispensed the medicines and in some cases he went out with him to assist him, as for instance he did in a case of fractured pelvis. Johnson derived no other income from the dispensary than the £1 per week which he paid him, though he believed he received some sort of payment for the assistance he gave his sister-in-law.

Cross-examined by Dr. BATEMAN witness said that since the issue of the new notice of this Council with regard to unqualified assistants he had told Johnson not to prescribe for anyone. Although in his time Johnson had attended many midwifery cases he had never attended any for him. As Johnson had been an assistant for twenty-three years he could scarcely be described as a medical student. It was the case that the certificates of witness had been placed in the window, but that was because a rumour had been spread about the neighbourhood that if any of his patients died there would be an inquest and the place would be shut up.

By Mr. MUIR MACKENZIE: When he engaged Johnson in May the latter solemnly declared that he had never treated patients at the dispensary and among other things he said he had sent a case of broken arm that came in to Mr. Tomlin.

By Dr. GLOVER: Witness attended all scarlet fever cases though he might send Johnson to see that the disinfection was carried out.

Mrs. ELIZABETH JOHNSON was next examined. She explained that her deceased husband had let the room to several medical men, including one who was a member of the Medical Defence Union, and that since she became a widow she had paid the rent and rates.

Mr. WARD read a declaration from Mr. Alfred William Johnson in which he denied that he had ever attempted to practise. As to Tyrrell he saw at once that there was very little the matter with him. If there had been anything serious about him he should have referred him to Mr. Mostertz.

The Council having deliberated *in camerâ* on the case,

The CHAIRMAN announced to Mr. Mostertz that the decision was that the charge had been proved to the satisfaction of the Council, but the Council had taken the matter into consideration and determined to adjourn further proceedings until next session when he would be cited to appear and would have to show that he had dissolved his connexion with this person whom he had been employing as an unqualified assistant.

The Council then adjourned.

MONDAY, NOV. 29TH.

The Council resumed to-day, Sir WILLIAM TURNER acting as chairman.

Preliminary Examination—Important Resolutions.

Dr. BATTY TUKE submitted a report from the Education Committee on the measures to secure a higher standard of preliminary examination for intending medical students. He said that before he read the report he would state the general principles which had actuated the committee in framing it and he thought he might be allowed to foreshadow as far as possible the policy which the committee thought should be followed by the Council in dealing with preliminary examination. In order to do this he must ask the Council to allow him to give a *résumé* of the work done during the last few years. He should speak of that work only since the establishment of the Education Committee. That preliminary examination had received a great deal of attention was marked by the fact that it had been the subject of no fewer than ten reports. He did not propose to go into the details of all these reports but would confine himself to a general outline. They showed that the Council had insisted upon candidates having a knowledge of mathematics (including arithmetic), of Latin, of one modern language, and of English. These were the subjects prescribed by the Council and were the subjects which were now demanded by the Council. They had been prescribed in general terms because the Council thought it was better to leave to the genius of each examining body to determine how the examination was to be carried out. But in order to preserve its hold on the examinations year by year the committee had overhauled the subject and reviewed the subjects of examination with the object of suggesting improvements. They had erased the names of some examining bodies and they had added new bodies. They had also effected an alteration in procedure by ordering that all the subjects should be passed at one time with, he was informed, very good results indeed, for it had eliminated from various examinations the weaklings—men who had gone up for examination time after time in the hope of passing at last. On the whole there had been during the last nine years a general improvement. That it was so was shown by the gradually increasing standard, the characters of the questions, and the increased percentage of rejections. But notwithstanding the improvement he was sure he expressed the general view of the committee when he said that the time had come when it was not only necessary but highly desirable that the standard of preliminary examination should be raised still further. The question had long exercised the minds of the committee. The great difficulty they had had to face was how was the change to be carried out. They were agreed that the standard should not be raised suddenly, but that the more cautiously and more carefully they proceeded the more likely was their action to be successful. The Council must remember that they possessed no power of insisting on preliminary examination and they had no statutory power of enforcing registration. That nowadays all medical students passed preliminary examinations and registered was due not to Statute but to recommendations of the General Medical Council and to the recognition of these by the various educational and licensing bodies of the kingdom. Preliminary examination and registration had become part of the system of medical education and registration, owing to the cautious action of the General Medical Council and the loyalty of the bodies. Still there was another thing that should be remembered and that was that no legislation could succeed that was in advance of public opinion. He thought it would be seen that no legislation in connexion with preliminary examination could proceed in advance of the general educational condition of the country. He was quite willing to admit that at one period of its deliberations the committee hoped to be able to submit to the Council a recommendation by which the standard of the preliminary education would be raised to a higher degree than that recommended in the report to this session, but they found that if not absolutely impracticable it was at least inexpedient to recommend any such step at present. They believed that any such step would dislocate the existing arrangements of bodies which had acted loyally towards the Council, and, moreover, that the general educational condition of the country would not warrant a sudden jump. At the same time the committee kept steadily in view the necessity there was that the standard of medical examination should be raised. They thought that all minimum examinations should be brought up to the level of those accepted by the universities, realising the fact that the standard of preliminary examination was not only being raised but would be still further raised. What he hoped was that after the lapse of a certain number of years under the conditions now recommended the Council would be in a position to exclude all junior examinations and accept only the senior examinations of the universities and governing bodies; and he anticipated after the lapse of a further period that they would find themselves in a position to advise all the bodies to institute a preliminary scientific examination which would include not only the subjects of general knowledge but also the subjects of chemistry and physics, leaving the full five years for strictly professional study. The report, which he would now read, was as follows:—

On June 9th, 1896, the Council agreed to the following motion:—"That the Education Committee be requested to consider whether the time has not come for erasing from the list of recognised preliminary examinations the 'Examination for a Second-Class Certificate (of First or Second Division) of the College of Preceptors.'"

Digitized by Google

This motion formed the subject of a report presented to the Council on Nov. 25th, 1896. In this report the committee expressed their opinion that it was inexpedient to make more stringent the conditions applicable to one of the recognised examinations without imposing the same restriction on the other examinations of the same grade; but they concluded the report by making two recommendations to the Council, the second of which forms the subject of the following report. The terms of this recommendation are as follows: "That the Council instruct the committee to consider the requirements of the several junior preliminary examinations now recognised by the Council and to report on the steps that may be necessary for enforcing a higher and more uniform standard therein; that the recommendations which the committee may propose with this object be brought before the Council at the November Session of 1897 in order that if approved they may be brought into force on Jan. 1st, 1900."

This recommendation was adopted by the Council after substitution of the words "at the earliest possible date" for "January 1, 1900."

The result of the inquiries the committee have conducted during the past year is that the minimum standard of certain of the junior examinations in general knowledge now recognised by the Council is insufficient to guarantee such a degree of general education as is desirable for persons entering on the study of a liberal profession, and that a considerable number of medical students receive certificates of having passed such examinations though they obtain low marks in particular subjects. The committee have had under review not only the questions submitted to candidates in these examinations, but also in certain instances the written answers of candidates who have passed on the lowest marking. The latter method of inquiry especially served to convince the committee that the general standard of these examinations is too low. The committee have to thank the Examining Boards, and in particular the College of Preceptors and the Scottish Educational Institute, for the facilities afforded them for conducting their inquiries. Various educational authorities have also been consulted and their general opinion is that the minimum standard of the preliminary examinations should be raised; that no difficulty stands in the way of doing so provided due notice be given to the public and that the effect of such a measure might be expected to have a beneficial effect on school education in general. The Reference instructs the committee to consider the requirements of the several junior preliminary examinations and to suggest steps which might lead to their improvement. After deliberation the committee have come to the conclusion that it would be impracticable to obtain a higher standard in the lowest class of these examinations by merely enjoining a higher pass-mark in any or all of the required subjects. The examination papers themselves are in general of too elementary a character, being evidently adapted to the ordinary capacity of pupils of less than fifteen years of age.

The committee are of opinion that the best means of securing the object in view is in the first instance to insist on a higher class of examination, the preparation for which must imply more extended training and wider study such as might fairly be expected to have been undertaken by students who had at least attained the age of sixteen years. The various local and matriculation or entrance examinations conducted by the several British universities are in general of this character; they include the required subjects prescribed by the Council, usually with others that are educationally related to them; and the regulations under which they are conducted are, in the opinion of the committee, adapted to ensure fuller and more mature school education in the candidates who succeed in passing them. The standard of examination the committee think desirable now to fix is such as can be readily passed by an average pupil on leaving the form next below the highest of a good school, and this standard they believe can and ought to be attained at the present time by students proposing to enter the medical profession. The committee do not suggest any increase in the number of obligatory subjects to be taken up by candidates, believing that if a student stands the test of a sufficiently searching examination in English, Latin, Mathematics, and in Greek or a second modern language he will be prepared to commence the study of the various sciences ancillary to medicine. The committee, however, recognise that it may before long be desirable to raise still further the minimum standard of preliminary education in such wise that no examination of lower standard than (for example) the senior local and higher grade examinations should continue to be recognised by the Council. These latter examinations are adapted to the capacity of students of about seventeen years of age, and require a wider range of study and a more detailed knowledge of particular subjects than the junior local examinations and certain of the university matriculation or entrance examinations. If the recommendations of this report be adopted by the Council the committee propose to watch carefully the effects thereby produced on the general education of medical students, to accumulate information on the subject from the various educational authorities, and thus to obtain materials for reports to be presented from time to time to the Council on the practicability of a further advance. For these reasons the committee have resolved to advise the Council to confine its recognition on and after Jan. 1st, 1899, to such examinations as the local and matriculation or entrance examinations conducted by the universities of the United Kingdom and to the examinations of corresponding standard held by the College of Preceptors, the Scottish Education Department, and the Intermediate Education Board of Ireland; and to intimate to other bodies in the United Kingdom and to the Indian, colonial, and foreign examining bodies that on and after the same date no examination of a lower class than those above referred to will be recognised by the Council.

The following are the examinations conducted in the United Kingdom which are regarded as at present of a lower standard than that which should be required:—

Royal Colleges of Physicians and Surgeons in Ireland.—Preliminary Examination.

College of Preceptors.—Second-Class Certificate of First or Second Division.

College of Preceptors.—Preliminary Examination for Medical Students (standard of Second-Class Certificates).

Educational Institute of Scotland.—Preliminary Medical Examination.

So far as the United Kingdom is concerned the step now proposed, if it be approved of by the Council, will serve to secure a higher and more uniform standard of preliminary examination; but it is manifest that as regards the Indian, colonial, and foreign universities and colleges the procedure will require some time. Not only must due notice of the impending change be given to these bodies, but the new standard of examination must be indicated to them, and they must have time to re-arrange their regulations and to satisfy the Council that their amended examinations are worthy of recognition. On the receipt of evidence to this effect the committee will prepare and issue a list of examinations which they regard as of sufficient standard. The committee are therefore of opinion that it would not be expedient for the Council to enforce the new standard of preliminary examination before Jan. 1st, 1899.

The committee submit the following recommendations:—

1. That the Council intimate to all the examining bodies whose examinations in general education are recognised by the Medical Council as qualifying for the registration of medical students that on and after the 1st day of January, 1899, no certificate of lower standard than that of the matriculation or entrance and the junior local examinations of the universities of the United Kingdom will be accepted for registration.

2. That the Education Committee be instructed to revise the list of examinations recognised by the Council with a view to removing from it on the 1st day of January, 1899, those examinations which are of a lower standard than that indicated in Recommendation 1.

He (Dr. Batty Tuke) moved the adoption of the first of these recommendations.

Dr. MACALISTER seconded the motion.

Mr. BRYANT agreed entirely with this admirable report. He was exceedingly pleased at it, for he felt with the committee that it was desirable gradually to raise the standard of education. He was also pleased to know that the Conjoint Board of the Royal Colleges of Physicians and Surgeons in Ireland was willing to conform to the wishes of the Council and drop their preliminary examinations in arts and that the College of Preceptors and the Educational Institute of Scotland were willing to help the Council in this matter. He thought there was little room for criticising the report.

Mr. TICHBORNE pointed out that while the Apothecaries' Hall of Dublin was the first of the professional bodies to drop the preliminary examination in general knowledge the Royal Colleges of Ireland were the last.

Mr. BROWN thought that the report was a step in the right direction, but he must confess he was disappointed in finding that the committee had not seen fit to increase the number of compulsory subjects. It would, in his view, have been greatly advantageous to the profession in the future if they had recommended the French language as an obligatory subject.

Dr. BRUCE did not quite agree with Dr. Batty Tuke that the Council had no power over the preliminary examination. He thought the Medical Act gave them power of the kind.

Sir RICHARD THORNE had listened with a good deal of attention to Dr. Batty Tuke's opening statement, but he must say that during it and the reading of the report his hopes underwent considerable oscillation, now rising and now falling, as Dr. Tuke proceeded. Dr. Tuke in one breath would tell the Council the extreme importance that existed of raising the standard; in the next he would caution them that education should not go in advance of public opinion. He entirely disagreed with Dr. Batty Tuke there, for he thought that education should be just so far in advance of public opinion as to lead public opinion. He had no hesitation whatever in saying that the advance which they had made in the elementary education which was necessary for entrance to the medical profession, so far from having gone in advance of the general education of the country, had lagged behind in the most lamentable, the most deplorable manner. They were cautioned that a rise in the standard of examination might lead to depletion of medical students. He could not see that there would be anything more advantageous to the profession than depletion. He knew that there were many Oxford and Cambridge men hanging about hospital doors without being able to find work to do, and what was wanted was depletion not only of medical students but of those who had not even the education of an ordinary gentleman. Adverting to the option the candidate now has of taking "Greek or a second modern language" he pointed out that if the modern language was selected it would be only one in addition to his own, which naturally he ought to know. He did wish that either French or German was made a compulsory subject. Nowadays there was such a vast amount of medical literature in French or German that members of the profession should have knowledge of one of these languages, if not of both, so as to be able to go for their information to the original and not be dependent on translations. Apart from these points he did not think the report was altogether logical. He read that "the committee have come to the conclusion that it would be impracticable to obtain a higher

Digitized by Google

standard in the lowest class of these examinations by merely enjoining a higher pass mark in any or all of the required subjects. The examination papers themselves were in general of too elementary a character, being evidently adapted to the ordinary capacity of pupils of less than fifteen years of age." These examinations were perfectly hopeless. If they were hopeless and could not be raised it was certain that the recommendation they were discussing did not bear on the matter and, unless he misunderstood, when taken in connexion with that paragraph was hardly consistent. If he were asked for an amendment he should have to ask the Education Committee to point out the examinations which being hopeless could not be accepted.

Mr. BRUDENELL CARTER said he would be very glad to fall in with the suggestion made by Mr. Brown that at least the French language ought to be made obligatory. He did not think it would be possible to make it one of the compulsory subjects for 1899, as the interval would not be sufficient to allow candidates to prepare; but all the same they should decide that in some not distant year French should be compulsory. He should prefer French to German. At the same time he should be very glad if the Council could see its way to enforce a really high standard in the English language. The knowledge of English possessed at present by the profession generally was not extensive enough. It seemed to him that students should be encouraged to know more about it seeing that they had to think and speak in it and as practically it was the first requirement of the medical men of this country. The recommendations might be modified to secure compulsorily a better knowledge of English and knowledge of French.

Dr. LEECH considered that all the members of the Council would be glad that the committee had gone so far that some of them were disappointed that it had not gone further. It was perhaps not very satisfactory to find that the standard of examination which the committee thought desirable was such as could be "readily passed by an average pupil on leaving the form next below the highest of a good school," but it seemed to him that if a boy learned mathematics well and passed a good examination in Latin, English, and Greek he did enough. He would not put any further subject compulsorily upon him.

Sir WILLIAM THOMSON, as a member of the committee, had nothing special to say about this report. A report of this kind was always one of compromise and in the present case the members of the committee sat for three days and discussed the *pros* and *cons.* of the matter with a great deal of earnestness. What he particularly rose for was to express his agreement with Mr. Carter in regard to the necessity that existed for a higher standard of English in the medical profession and also to express his sympathy with the proposal to make one of the continental languages an absolutely compulsory subject, preference being given to French. The reference to the committee did not include these matters, but they were such that the committee might well consider them and take such steps as to increase the value of the examination they now recommended.

Dr. MACALISTER, replying on the whole debate, was glad that the general principles of the committee's procedure had met with a fair amount of approval on the part of the Council, though the points raised by Sir Richard Thorne showed that the argument was not stated so clearly as it might be. What the committee were asked to do was to examine the various junior examinations—that was to say, those that were not senior or called senior. When they looked into these examinations they found that there were two well-marked levels—one representative by the local examinations of most of the universities, all of which were pretty fairly of one standard and were regarded as fairly equivalent of each other; the other class represented by examinations of a standard lower than the university local examinations. A little investigation showed that the papers and the second class of examinations were of such a character that if even full marks were awarded for them that would not be sufficient to meet the object in view. Consequently, merely to insist upon higher marks would not have improved things, neither would any increase in the number of subjects. So the committee had decided as the report set forth. With regard to the amount of change which was involved he thought the gravity of it was not fully appreciated. The step proposed to be taken was not quite a small one. The students who were examined and registered yearly numbered something like 1600, and of that number 480 or so passed on to registration by means of those examinations which it was intended to recognise no longer as sufficient. Accordingly when it was seen that at one stroke they cut off more than a fourth of the number which at present secured registration as students the gravity of the step would perhaps be a little more appreciated than it seemed to be. As to making French obligatory, his opinion was that if that were done it would result practically in leaving out Greek. He would prefer to see logic rather than Greek struck out. They had endeavoured five years ago to get logic omitted from the optional subjects, but at that time they were unsuccessful. He should not be sorry to see it go now.

The recommendation was then put and unanimously adopted.

Dr. BATTY TUKE next moved the committee's second recommendation. He expressed the wish that they could have brought the new system into operation more speedily, but that was out of the question owing to the amount of correspondence that the change would involve.

Dr. MACALISTER seconded, and after a remark by Sir RICHARD THORNE about men getting through with a sixpennyworth of logic.

The second recommendation was also unanimously agreed to.

On the motion of Dr. BATTY TUKE, seconded by Sir RICHARD THORNE, it was further agreed:

That on and after Jan. 1st, 1899, Logic be omitted from the list of optional subjects in the preliminary examination.

Mr. BROWN thought the feeling of the Council was favourable to a motion for the inclusion of French amongst the compulsory subjects, say, from the year 1901.

The CHAIRMAN was of opinion that this matter should not be pressed at present but should be left to the committee.

Dr MACALISTER indicated that adequate means would be taken to let the educational world know of the changes they had just agreed to.

Sir CHRISTOPHER NIXON moved:—

That it be referred to the Education Committee to consider and report to the next session of this Council the procedure necessary for the institution of a preliminary examination for medical students of a standard uniform throughout the United Kingdom, such examination to be wholly conducted by the General Medical Council.

In supporting this proposal Sir Christopher Nixon said that it was only a few hours since he learned from his friend Sir William Thomson that in the session of November a year ago Sir William Thomson himself had moved a resolution somewhat to the same effect, and as he would not like to steal Sir William Thomson's clothes while he was bathing it would be only fair of him now to give Sir William Thomson the option of taking up the motion. (Sir William Thomson indicated that he had no wish to do so.) Then, Sir Christopher Nixon went on to say, the reason why he proposed the resolution was that the present mode of holding examinations seemed to him to be largely responsible for what he might call the degradation of the profession and to a large extent instrumental in the production of those penal cases which absorbed so much of the time of the Council. He was quite aware of the desire of the Council to raise the standard of preliminary examinations by every means in its power, but even the debate they had just been engaged in showed how little power the Council had in connexion with these examinations or in securing what was so important—a minimum standard. There were so many bodies conducting these examinations which the Council did not inspect—had not, he supposed, the power to inspect—and which he did not think could in any way be regarded as uniform in standard. The percentage pass was low—33 per cent. in some cases—and the result was that at the very entrance to the profession they had men cramped by a deficiency in elementary knowledge. He thought the report just adopted was of such a character as to imply that the Education Committee would not be remarkably successful in securing their object. To his mind the only way of attaining that object was to establish an examination which would be absolutely controlled by the General Medical Council. Short as his acquaintance with that Council was, he had seen enough to convince him that there was no other body—at any rate, none he knew of—to whom he would more willingly entrust the interests of the profession.

Mr. HORSLEY formally seconded the motion.

Sir WILLIAM THOMSON did not like to express his entire approval of this proposal. He was afraid that at the present moment the Council had no power to carry out such a scheme.

Digitized by Google

It was certainly a scheme in which he personally took the greatest interest, but a modification of the Act of Parliament under which the Council acted would be necessary before effect could be given to it.

Mr. BRUDENELL CARTER, who mentioned that he had always entertained the view that the profession should keep the key of its own door, remarked that he should be exceedingly glad if the suggestion in the proposal was one that could be adopted as he was quite sure that to place it in the power of the General Medical Council to carry out the reforms that were now required would add immensely to the culture and dignity of the profession.

Dr. CHURCH looked upon the proposal as a dangerous one. Supposing it were competent for the Council to conduct the preliminary examination for the medical profession he thought the area too wide to be undertaken by one body. He thought a higher standard of education was now possible by the competition among educational bodies that went on at present than could be obtained if there was only one body controlling the whole set of examinations. He for one could not agree that it would be wise on the part of the Council either to fix the standard of preliminary examination for candidates for the medical profession or undertake the labour of maintaining that standard.

Mr. TEALE pointed out that the direction in which the Council had hitherto gone was to put the preliminary examination in the hands of the educational bodies thoughout the country and more particularly in the hands of the universities. He saw no reason why they should make a change. Though they understood medical education the General Medical Council were not the body to undertake general education.

Dr. LOMBE ATTHILL thought that if Mr. Teale's views were carried out it would simply mean that the medical education would fall into the hands of the universities.

Sir WILLIAM TURNER: Oh, no.

Dr. LOMBE ATTHILL was sure the Council would never attain an efficient standard of education until they had examining boards for the different parts of the kingdom which they themselves controlled and could visit and inspect.

Dr. MACALISTER wanted to know if the mover and seconder of the proposal had ascertained whether there was legal power to give effect to their proposal and whether they were prepared to start a school with the object of securing the fitness of candidates for the examination suggested.

Mr. HORSLEY pointed out that all the motion did was to ask the Education Committee to consider and report upon the procedure that it would be necessary to adopt to institute and carry on a preliminary examination to be conducted by the Council. Neither he nor the mover intended to raise the general question of the advisability of entering upon such a scheme. Both he and Sir Christopher Nixon, both new members, were ignorant of what the procedure necessary would be and they wanted information. That practically was all the motion amounted to.

The CHAIRMAN: The motion certainly does involve the institution of an examination by this Council.

Dr. BATTY TUKE: This is not a matter for the Education Committee at all. It is one for the legal advisers.

Mr. HORSLEY: If the Education Committee find that any legal point is involved they could consult the legal advisers. All we ask is that the Education Committee consider how it could be done. I do not see that this motion binds the Council to anything.

Dr. MACALISTER: Six months hence it would be held that it did bind the Council.

Sir WILLIAM TURNER said there was no doubt that it had been the aim of the Council to leave examinations in arts to the educational bodies. It would be rather inconsistent after their efforts to get the licensing medical bodies to give up their preliminary examinations for the Council to come in and say that it would itself now take over the whole of the preliminary examinations for medical students.

Dr. LEECH objected to any resolution which would lead to the General Medical Council undertaking the preliminary examination. Such a change in the present system would do education a great deal of harm and no good.

On a division the motion was rejected by 19 votes to 7, 2 members declining to vote.

Accumulation of Examinations.

The next business on the notice paper was the following:—

Report of a conference between the Examination and Education Committees on Mr. Teale's motion of June 2nd, 1896: The Examination Committee begs leave to report that in conformity with the wish of the Council it has conferred with the Education Committee. Pending additional information on the subject it is not prepared to make any recommendations at the present session, but asks leave from the Council to continue the reference.

Sir DYCE DUCKWORTH, as chairman of the Examination Committee, in moving that the report be entered on the minutes, said that last session it was decided that a conference should be held on a point which was referred to the Examination Committee and which caused so much interest and attention when raised by Mr. Teale in what he (Sir Dyce Duckworth) would call his (Mr. Teale's) celebrated motion on the accumulation of examinations. That motion referred to the large number of rejections at examinations which it was said was believed to be caused by the great pressure of examinations the students were subjected to. That matter had been considered by the Examination Committee and a report had been submitted to the Council who had authorised the conference. The matter had not been lost sight of. It would still be under the notice and discussion of the Examination Committee, who already had held a conference with the Education Committee without much coming from the meeting. The whole point was conceived to be, What position is to be held by scientific and preliminary subjects? That would be carefully considered, but it was necessary that the Council should give leave to continue the reference and let a report be prepared.

Dr. PETTIGREW seconded.

Mr. TEALE wished to remind the Council that when proposing his motion he had stated distinctly that he did not expect an immediate result. The motion was put forward rather to draw the attention of the Council and bodies concerned to the question in the hope that something might be done when the curriculum or any part of it was under consideration.

Sir DYCE DUCKWORTH'S motion was agreed to.

Penal Powers of Licensing Bodies.

Mr. BRYANT, on behalf of the Executive Committee, submitted the following report on the penal or disciplinary powers of the licensing bodies:—

The Executive Committee have pleasure in reporting that some progress has been made in regard to this question since the Interim Report was received last session. With reference to the English Universities a communication has been received from the University of Durham informing the Council that a Charter, dated Aug. 25th, 1897, has been granted from which the following Sections have been extracted:—

"Whereas doubts have arisen whether the Warden, Masters, and Scholars of the University of Durham have power to cancel, revoke, annul or take away any degree or title conferred by the University of Durham upon any person who shall have been proved to be unworthy to be a Member or Graduate of a University, and whether such power was at the date of the Charter first hereinbefore recited and now is a right or privilege incident to a University established by Royal Charter. And whereas it is expedient to remove such doubts as aforesaid. ..... Now know ye that We do of our especial Grace, certain Knowledge and mere motion by these presents for Us, our Heirs and Successors will grant, ordain and declare that the said Warden, Masters and Scholars of the University of Durham shall be empowered and are hereby authorised and empowered to cancel, annul, revoke, and take away any degree or title that has been or shall hereafter have been conferred by the University of Durham upon any person of whom it shall be reported to Convocation by the Warden and Senate that such person has been convicted of a crime for which he has been sentenced to penal servitude or imprisonment and that such crime is one which renders him unfit to be a member or graduate of the University of Durham."

It has also been intimated to the Council that the Court of the Victoria University has decided to apply for similar powers to those already obtained by the University of Cambridge, and that now it only remains that the application should be formally made to the Crown with every prospect of the power being conferred. With reference to the Scottish Universities the President has informed the Council that the Edinburgh University Court has again considered the question of obtaining power to remove from the roll any graduate who may be found guilty of a criminal offence or other misconduct; and the Court has decided to intimate to the other University Courts that, while remaining of opinion that the difficulties of the question are very great, it is willing to confer with the other universities and to appoint representatives to a joint committee which might report to the various courts. An official communication has been received from the University of Glasgow stating that the Court on July 8th, 1897, adopted a memorandum in which it desired very respectfully to raise the question whether it might not be possible for the Universities Commissioners even now, without determining anything, to leave on record in their final report such an expression of their opinion as may tend to bring the Scottish Universities into line with each other or with those universities of the United Kingdom which either already possess or have expressed the desire to obtain further disciplinary powers in accordance with the expressed wish of the General Medical Council.

The Glasgow University Court is fully aware of the difficulties of the subject and has made no attempt to disguise or to over-ride these in its communications to the General Medical Council. The court is also willing, nay, desirous, that the whole subject should be fully discussed from the point of view of the other Scottish universities, so that any attempt made after the expiry of the Commission to meet the

Digitized by Google

wishes of the General Medical Council in respect of disciplinary powers may proceed as a conjoint movement on the part of all the Scottish universities. But it appears to this University Court that in no way could this desirable object be more facilitated than by an expression of opinion, after due inquiry by the Universities' Commissioners, to be included in their final report. The Glasgow University Court will be willing to place itself at the disposal of the Universities Commissioners should it appear desirable to take evidence or to bring about in any way a conference of the Scottish universities with respect to the questions involved in this memorandum. The Scottish Universities Commission in answer to the Glasgow and Aberdeen Courts, however, assert that the matter to which the above memorandum refers is not within the province of the Commission. They have no Parliamentary powers to deal with it or instructions to report upon it. In the Joint Committee referred to above all the universities of Scotland would no doubt take their part and thus united action be taken by all the Scottish universities. So far no information has been supplied to the Council as to any further steps taken by the Royal University of Ireland.

In moving that this report be entered on the minutes Mr. Bryant said there had been a first report on this subject, then an interim report, and now this further one, which he should like to distinguish as the third report. It simply gave information to the Council of what had been done by the different licensing bodies since last May. He was happy to say that it was favourable. He hoped that when the subject was again reported upon there would be something more definite to say.

In answer to Dr. MCVAIL Sir CHRISTOPHER NIXON said that the Irish University authorities considered they could do nothing in this matter unless they had some new powers.

Dr. MCVAIL suggested that they should inform the committee of their view.

Sir DYCE DUCKWORTH seconded Mr. Bryant's motion, which was agreed to.

The CHAIRMAN said no further motion on the subject was needed seeing that the report was only narrative.

The Case of Alfred Freeman.

The Council proceeded to the consideration of the case of Alfred Freeman, of 163, Bloomsbury-street, Birmingham, registered in England as Mem. R. Coll. Surg. Eng. 1862; Lic. R. Coll. Phys. Edin. 1879, who had been summoned to appear before the Council on the following charges, on the complaint of Albert Henry Bygott, of 1, Deritend, Birmingham, registered in England as Lic. Soc. Apoth. Lond. 1893:—

(1) The complaint is in respect of two dispensaries or establishments where branch medical practices are carried on in the name of Mr. Freeman at 65, Benacre-street and 163 and 165, Bloomsbury-street, Birmingham. (2) The complaint is that at such establishments or dispensaries Mr. Freeman, being a registered practitioner, authorises, permits, and enables two unqualified and unregistered persons, who purport to act as his assistants, to attend upon and administer medical treatment to patients and give and sign medical certificates in his (Freeman's) name and carry on medical practice as if they had been duly qualified and registered. (3) The unqualified persons referred to were his (Alfred Freeman's) two sons. (4) The complainant is Mr. Albert Henry Bygott, of 1, Deritend, Birmingham.

Mr. Bygott appeared to support his case and Mr. Freeman was assisted by Mr. Meade, solicitor.

Mr. BYGOTT made a statement as to the position of the two dispensaries and Mr. Freeman's residence and the manner of practice carried on in the former and presented to the Council certain declarations.

Mr. FREEMAN went into the witness-box and tendered evidence. He said he had been thirty-four years in practice; of this time twenty-nine years being spent in the town of Wolverhampton, where he had been a member of the town council. About two years ago he went to Birmingham, taking up his residence and practising at Bloomsbury-street. He afterwards changed his residence to Nechell's-green and opened the surgery in Benacre-street. One establishment was taken by his eldest son, who was thirty-two years of age, and the other by another son, eighteen years of age, but both were conducted under his close personal supervision.

The Council decided that the case had been proved and directed the Registrar to erase Mr. Freeman's name from the Medical Register.

Thereafter the adjournment took place.

TUESDAY, NOV. 30TH.

On taking the chair Sir WILLIAM TURNER said there was a good deal of business on the programme, some of it of considerable importance, and he would express the hope that members would address themselves closely to the points so that they might finish the session that day.

The Pharmacopœia.

Mr. H. E. ALLEN, the Registrar, read the following report from the Pharmacopœia Committee:—

The committee having had entrusted to it the duty of preparing the new edition of the British Pharmacopœia has now the honour to submit for the approval of the Council copies of their final draft of the work subject to the correction of typographical and other errors. The estimated amount to be expended on its production will be about £6000. If 20,000 copies are printed the cost to the Council will be about 6s. per copy. The committee accordingly suggest that the price of the volume might suitably be 7s. 6d., but the power of actually fixing the price rests with the Commissioners of the Treasury. In order that the Pharmacopœia may be issued early next year the committee recommend that it be delegated to the Executive Committee to adopt the fully corrected work as "The British Pharmacopœia, 1898," to communicate with the Commissioners of the Treasury on the question of price, to publish the Pharmacopœia, and to make the legal announcement of publication by notice in the London, Edinburgh, and Dublin Gazettes in accordance with the provisions of the Medical Act, 1862.

This report having been entered on the minutes.

Mr. BRUDENELL CARTER moved the adoption of the recommendation which it contained. In so doing he said that as it was not in his power to practically render any other assistance to the Pharmacopœia his colleagues on the committee had been kind enough to put him in the chair when their President (Sir Richard Quain), who was chairman of the committee, was absent. That had given him the opportunity of seeing with what painstaking care the new edition of the Pharmacopœia had been produced. On the production of no previous edition of the work had anything like the same labour, pains, and care been bestowed, and he felt quite confident that it would remain as a monument of the greatest possible credit to this Council. The book now was entirely complete with the exception of typographical corrections, and the committee therefore asked the Council to refer to the Executive Committee the special function of ordering it to be published. Unless they secured an arrangement of this sort with the Executive Committee the publication of the book would have to be deferred until the end of May. They felt that the necessary corrections could be made before the next meeting of the Executive Committee in February, 1898, and that it would be in a fit condition to be published. The book would cost 6s. 2d. per copy and the price at which it was to be sold to the public might be higher than the 7s. 6d. named in the report. That was a matter that rested with Her Majesty's Treasury, but personally he thought that the price of 10s. or 10s. 6d. would probably not be too much to pay for a work of the character in question.

Sir DYCE DUCKWORTH, in seconding, said it was due to the Council that they should know what an immense amount of labour and pains had been taken in connexion with this new edition of the Pharmacopœia and how much painstaking labour had been bestowed upon it by their esteemed President himself. Those who knew Sir Richard Quain knew what pride he had taken in the production of each successive book in the preparation of which he had taken part and he felt sure that if Sir Richard Quain had been able to be present he would have told them something in detail of the work which had been carried on during the last few years. The labour had been simply stupendous. The committee had been materially assisted by the painstaking work of Dr. Tirard, who had had the most of this large work in his hands during the last two years. The book would not now have been so well advanced as it was but for the work Dr. Tirard had done. This edition of the book had been revised in a way that no previous Pharmacopœia had been. In making it such a complete work as it would be they had had the assistance of Indian and colonial authorities and it was really the first Imperial Pharmacopœia. Altogether the labour bestowed upon its production was unprecedented and it was a work that ought to command the utmost confidence. The book was worthy of the Council and he hoped that every member of the profession would provide himself with a copy of it.

Dr. MACALISTER cordially agreed with all that had been said.

Mr. BROWN asked what was the price of the present edition of the Pharmacopœia.

The CHAIRMAN replied that it was 6s., but it was being sold for 4s. 6d.

Mr. BROWN thought it would be a big jump if they raised the price of the book from 6s. to 10s.

The CHAIRMAN said that under the Act of Parliament it

Digitized by Google

rested entirely with Her Majesty's Treasury to say at what price the book should be sold.

The motion was agreed to.

Dental Education and Examination.

On the motion of Dr. MACALISTER, seconded by Dr. LEECH, the Council went into committee for the consideration of the recommendations of the Dental Education and Examination Committee.

Mr. BRYANT explained that in December, 1896, the Committee presented a report; in May, 1897, they presented an additional report; and now they presented their third and final report. He had hoped to have been able to ask the Council to adopt this final report, but when he looked down the programme of business and saw the notice of motion in the names of Dr. Heron Watson and Dr. McVail he felt that to meet the resolution he should be obliged to go into details connected with all these reports and he suggested that the Council accept the final report as read and allow him to confine himself simply to the point raised by Dr. Heron Watson and Dr. McVail.

The CHAIRMAN thought the best course in the meantime would be for Mr. Bryant to read to the Council the final report.

Mr. BRYANT then read it, the terms of the report being as follows:—

This Report is based upon the "Additional Report" of this Committee which was presented to the General Medical Council in May last and was entered on its Minutes, together with the remarks upon it made by the four licensing bodies to which it was referred with the whole of the previous Reports bearing upon the recent inspection of their examinations. We have reason to believe that the Report of the Royal College of Surgeons of England will be favourable to the recommendations of this committee with respect both to the curriculum and to the examinations, but it cannot be communicated officially at present. Upon the recommendation of this committee that the Royal College of Surgeons of Edinburgh should unite with the Faculty of Physicians and Surgeons of Glasgow and so form one Conjoint Dental Board for Scotland, the Edinburgh College reports that the recommendation was carefully considered by the President and Council of the College and subsequently at the statutory meeting of the College on Oct. 20th, 1897, when it was resolved that the recommendation of this Dental Committee should neither be accepted nor even entertained by the College.

The Faculty of Physicians and Surgeons of Glasgow after referring it to their legal advisers likewise reports: "In view of the fact that there appears to exist no statutory provision for sanctioning the suggested combination and of the doubtful validity of a voluntary or non-statutory union of the two boards the Faculty consider that they are at present precluded from taking action in the direction indicated by this recommendation."

Under these circumstances this committee can only express its regret that its suggestion for providing one Dental Examination Board for each division of the United Kingdom cannot at present be carried out. With respect to the recommendation of this committee that the three months' course of materia medica should not be required, it would appear from the remarks of the Royal College of Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, that such an omission is not by them considered desirable; whereas the London Royal College is in accord with the recommendation and the Irish College seems to be indifferent to it as it passes it by. With respect to the recommendation of this committee that the courses of lectures in physiology, metallurgy, and mechanical dentistry should be helped by special practical courses, the Edinburgh Royal College of Surgeons states that the additional courses suggested already substantially exist in its curriculum although not directly specified under a separate designation, and "considers that the remedy for any supposed deficiency in such teaching will be found not in further sub dividing the courses in the curriculum but in securing that the courses as at present prescribed are thoroughly and efficiently utilised."

The Faculty of Physicians and Surgeons of Glasgow fully recognises the importance of practical instruction and that the changes recommended are generally in that direction. It thinks, however, that whenever practicable the practical instruction should be combined with the ordinary course, but approves of the addition of a practical course of dental metallurgy.

The London College already acts up to the recommendations and the Irish College has not raised any objections to them, consequently your committee leave these recommendations as they now stand with the assurance of the examining bodies that the practical part of the instruction will be effectively provided for.

The recommendations of this committee with respect to examinations are covered by the scheme of the London College and are not criticised by the Irish College. The Edinburgh College states that its First and Second Examinations comprehend substantially all the subjects suggested by this committee, although the order in which they are taken at the examinations may differ. The College criticises severely the suggestion of this committee that an examination in general medicine and therapeutics is not required. The Faculty of Physicians and Surgeons of Glasgow is of opinion that, assuming there should be a preliminary and two professional examinations, the grouping of the subjects under these examinations is on the whole judicious; but it considers that all the subjects of the dental curriculum can be sufficiently covered by the two professional examinations, but agrees with this committee that the practical tests in the examination should be increased in stringency. It, however, points out to the committee that there is no necessity for elementary chemistry to be included in both the preliminary—if instituted—and first professional examinations. The error was due to the omission of a note in the original report that chemistry would only be included in the first professional examination if it had not been passed in the preliminary. The faculty also complains that "on the important point of the extent and area of the examinations of dental students in such subjects as anatomy, physiology, and general surgery the recommendations of this committee give no leading and are of opinion that in such subjects the range of topics to be examined on should be less extensive than that for general medical students and be limited by some consideration for their practical application to dentistry."

The committee feels that it does not fall within the province of the Council to furnish anything like a complete syllabus of any part of the examination but would suggest that it should include, in addition to a thorough acquaintance with dental and oral anatomy, pathology, and surgery, a general knowledge of anatomy and physiology and of the principles of medicine and surgery with only such details in any of these subjects as may have a practical bearing upon the actual requirements of dentistry.

Your committee finally now present to the Council the recommendations as originally drawn up by the Dental Curriculum Committee in 1879 in regard to the education of the dental student, and corrected up to date according to the experience gained by one or other of the four dental licensing bodies. The deviations from the original scheme which have been adopted have, as it were, grown out of experience, and their results have chiefly been to encourage the practical branches of the dental art and to eliminate what has been found to be unnecessary. Neither radical changes in curriculum nor rigid methods in examination have been suggested, for your committee are well assured that so long as the examining bodies do not fall behind the main recommendations of this Council, either in the way of curriculum or examination, this Council has no other wish than that the details of the course of study and examinations may vary in the way which seems best to the governing authorities of the licensing bodies, all of which have full liberty of action. But this committee feels that all the bodies interested ought to work on the same lines. With these objects in view it is hoped that the recommendations of this committee will prove acceptable.

APPENDIX A.

AMENDED RECOMMENDATIONS OF THE GENERAL MEDICAL COUNCIL.

(1) In Regard to Preliminary Education Applicable to Dental Qualifications.

(*a*) The registration of dental students shall be carried on at the Medical Council Office in London or at the branch Council office in Edinburgh or in Dublin in the same manner as the existing registration of medical students and subject to the same regulations as regards preliminary examinations.

(*b*) Students who commenced their professional education by apprenticeship to dentists entitled to be registered, or by attendance upon professional lectures, before July 22nd, 1878 (when dental education became compulsory), shall not be required to produce evidence of having passed a preliminary examination.

(2) In regard to Professional Education.

(*a*) Candidates for a diploma in Dental Surgery shall produce certificates (i) of having passed a preliminary examination in General Education; (ii) of being twenty-one years of age; and (iii) of having been engaged during four years in professional studies.

(*b*) Candidates shall produce certificates of having passed through the following curriculum:—

(i) General Medical Subjects.

Anatomy, one winter session.
Dissections, twelve months with demonstrations.

Physiology, with a separate practical course, or with practical work introduced in the course. } one course
Chemistry, including Physics. } of
Surgery, including Pathology. } six months.
Medicine, }
Materia Medica, one course if thought necessary.
Practical Chemistry, one course of three months.

Attendance at a recognised general hospital with clinical instruction, not less than one year.

(ii) Special Subjects.

Dental Anatomy and Physiology, human and comparative, not less than twenty-four lectures, including Dental Histology and the preparation of Microscopic Sections.

Dental Surgery and Pathology, not less than twenty lectures.

Metallurgy, not less than twelve lectures, or demonstrations made practical, or with a distinct practical course.

Mechanical Dentistry, not less than twelve lectures, with separate course of Practical Dental Mechanics.

Practice at a Dental Hospital, or
Dental Department of a general hospital, two years.

(*c*) Candidates shall produce certificates of having received three years' instruction in Mechanical Dentistry from a registered practitioner.

(*d*) The three years of instruction in mechanical dentistry, or any part of them, may be taken by the dental student either before or after his registration as a student; but no year of such instruction in mechanical dentistry shall be counted as one of the four years of professional study unless taken after registration.

(*e*) One year's *bond-fide* apprenticeship with a registered dental practitioner, after being registered as a dental student, may be counted as one of the four years of professional study.

Mr. BRYANT having read this report moved that the amended recommendations as specified in the Appendix A be adopted.

Mr. CARTER seconded this motion.

Dr. MCVAIL suggested that the Council should before going into this matter deal with this:—

Notice of motion, to be moved in committee by Dr. Heron Watson, seconded by Dr. D. C. McVail: That this Council is of opinion that the suggestion of the Dental Education and Examination Committee that the Royal College of Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow should unite in conferring a single qualification in dental surgery is not provided for in the Dental Act

Digitized by Google

(Section 28 of that Act never having come into operation) and need not therefore be entertained by this Council, whose duties consist simply in administering the Act.

Mr. BRYANT said that the state of the case in this regard was that the committee made their recommendation. The bodies said they were not in a position to carry it out, but the recommendation stood and there was no reason why it should not remain on record in the report.

The CHAIRMAN asked whether, after this statement, it was necessary for Dr. Heron Watson to proceed with his notice of motion.

Dr. HERON WATSON took the view that it was necessary in order that the constitutional question might be made clear. In his opinion the committee had far exceeded its duty. Not only so, but he doubted whether this report was brought up in a form in which it could be dealt with by the Council. He did not see why the committee had not presented certain definite issues upon which the Council might express an opinion.

Mr. BRYANT then read to the Council the additional report presented in May, which is much too long a document to be reproduced in these columns. With regard to the question of materia medica which appeared to excite a good deal of interest Mr. Bryant said that in the case of his own College the general student was not required to attend a course of materia medica, and he thought they could not ask more from the dental student than they did from the general one in this respect. He did not think it was advisable to do anything which might give to dentists the idea that they were justified in administering drugs. They learned the work of their profession in the lectures and advice given to them in practical surgery. They were taught to write prescriptions, but his College did not wish them to write other than simple prescriptions of lotions and so on because there was no desire to suggest that they were justified in administering medicines for internal diseases. That was all Edinburgh seemed to require of their students—knowledge of narcotics, emetics, purgatives, depressants, and stimulants; and in the case of Glasgow they simply spoke of knowledge of therapeutics in relation to emetics and vomiting, including the modes of prescription and the medicines employed. The Royal College of Surgeons in Ireland seemed to eliminate it altogether. What the committee did was to leave materia medica an open question so that the College might include the subject or not as they wished. He could not see that there was any objection in leaving it standing. Let the Council remember that these were not requirements. They had no absolute power of compelling any one of these bodies to do this or the other thing; they could only express pleasure when they fell in with the Council's recommendations and regret when they took a different course. Moreover, he thought that so long as the bodies did not fall behind the recommendations of the Council they ought to be fairly satisfied. As to the suggestion that came from the Glasgow Faculty with respect to some sort of guiding as to the extent to which dental students should be required to go into anatomy, physiology, medicine, and surgery, and if the body wished it materia medica, he might say that at first sight he was so satisfied with it that he sat down at once to form some sort of syllabus of the subjects, but after a time he realised that it was not the function of this Council to draw up syllabuses or synopses for the examining bodies and he abandoned the idea, and the committee had contented themselves with the expression of opinion found in their report.

The CHAIRMAN said he could not help thinking that the committee should have formulated a series of specific recommendations so that a vote could be taken upon each and the opinion of the Council thus obtained. As it was he suggested that the Council was not ripe to come to a decision upon the report.

Dr. MACALISTER moved:—

That it be remitted to the Dental Education and Examination Committee to draw up their recommendations in the form of a series of propositions, each dealing with a single subject, in order that the Council may be enabled next May to come to a definite decision on this subject.

Mr. BROWN, in seconding this amendment, said that in the present state of the case the Council was not in his opinion in possession of sufficient information to come to a proper conclusion.

Sir RICHARD THORNE said that while he quite approved of what Dr. MACALISTER had proposed he would read to the Council a motion he had prepared on this subject. It was to this effect, viz.:—

That it be remitted to the Dental Education and Examination Committee to consider and report whether it is not possible and expedient so to restrict the curriculum for dental students as to make it less adapted to the practice of medicine and surgery and better adapted to the practice of dentistry.

Since he had been a member of this Council nothing had impressed him more than the encouragement given for the education of mongrel doctors. One day they were attempting to stop irregular practice and the next they were engaged in supporting the education of these men in medicine and surgery. He would say that nine-tenths of the work was not adapted to the dental profession and that it was mere waste of time for the dental student to occupy himself with it because he might be much more profitably employed.

After some further discussion the Council by a large majority adopted Dr. MacAlister's proposal both as an amendment and as a substantive motion.

The CHAIRMAN asked Mr. Bryant whether he intended to insist on the reference to the proposal to fuse the two Scotch bodies in order to constitute a single examination in Scotland.

Mr. BRYANT said he thought it well that it should remain on record.

Dr. HERON WATSON expressed the opinion that it should be removed.

Dr. MCVAIL said that what the Scotch bodies objected to was the suggestion that this idea of a combination had never occurred to them until it was put forward by this committee. As a matter of fact it had been discussed immediately after the passing of the Act and from time to time since by them and they had found that they could not possibly unite under the present Dentists Act.

Dr. MACALISTER pointed out that the report was not adopted by the Council and therefore the reference to this subject could do no harm.

The CHAIRMAN suggested to Mr. Bryant that in bringing up his new report he should make a point of putting the two bodies in their proper position and so disposing of this matter.

Mr. BRYANT acquiesced in the suggestion.

Dr. HERON WATSON said that in these circumstances he would not press the motion of which he had given notice.

The following motion also standing in the name of Dr. Heron Watson was not moved, viz:—

That this Council, while recognising the care and attention bestowed by the Dental Education and Examination Committee upon the consideration of the reports furnished by the inspector of dental examinations, desires to place on record that no occasion is shown for the suggested withdrawal of materia medica from the dental curriculum and from the list of subjects for examination, and that the substitution in its stead of the hospital attendance and general lectures and four years of practical work does not meet either the requirements or the approval of this Council; and further that the conclusion at which the Dental Education and Examination Committee arrives, "that an examination in general medicine and therapeutics is not required," the necessary teaching and learning of these subjects so far as they belong to the practice of Dentistry being included in the general scheme as laid down," is also contrary to the requirements and approval of this Council.

The Council having resumed confirmed Dr. MacAlister's proposal adopted in committee.

On the motion of Dr. HERON WATSON, seconded by Dr. MCVAIL, it was agreed that an honorarium, the amount of which was left to the decision of the Executive Committee, be voted to Mr. Tomes, together with the best thanks of the Council for his inspection of the dental examinations and his reports upon them and upon the requirements of the curriculum in the case of each of the bodies granting a registrable diploma in dentistry.

Public Health.

Sir RICHARD THORNE presented a report from the Public Health Committee. In this report the committee begged leave to advert to their report to the Council of May 27th, 1897, on the Scotch Public Health Bill, which report was adopted by the Council and forwarded to the Secretary of State for Scotland, the Lord Advocate, and each member of the Committee on Law of the House of Commons then sitting on the Scotch Public Health Bill. In that report the committee drew attention to the fact that the proposal embodied in Section 22 of that Bill to place the opinion of the sanitary inspector in matters where a judgment has to be formed as to what is or is not liable to constitute a danger to public health on a statutory equality with that of the medical officer of health was calculated seriously to frustrate the efforts which the Council had made to ensure a distinctively high standard of proficiency in the public health service. The committee now further reported that following on the action taken by the Council the reference to the sanitary inspector was altogether deleted from the section as it now stands in the Public Health (Scotland) Act, 1897, and that the

Digitized by Google

hitherto existing status of medical officer of health in Scotland in the matter referred to has been maintained. The only remark he desired to make was that, knowing, as he did, how extremely strong was the determination of some who were in very high positions to prevent the restitution of these rights to medical officers of health, he thought the Council was greatly to be congratulated on the result which could not fail to have its effect both in England and Ireland as well as in Scotland.

Dr. BRUCE, in seconding the motion, said that undoubtedly the action of the Council in this matter had been of great assistance to the medical officers of health.

The report was received and entered on the minutes.

Medical Aid Associations.

Dr. GLOVER read the following interim report from the Medical Aid Association Committee, namely:—

The Committee on Medical Aid Associations have to report to the Council that they have met deputations from Norwich and Yarmouth and have conferred with them on the memorial on the subject presented to the Council. On the suggestion of Mr. E. W. Brabrook, the Registrar of Friendly Societies, the committee has had an interview with a sub-committee appointed for the purpose by the leading friendly societies at which an opportunity was given for a full expression of opinion on the matters in dispute between the members of the profession and the associations. In the result a desire was expressed that the subject should be still further discussed in a similar conference to be held in the course of a few weeks. In view of such conference and of the need for further consideration of the matter by the committee the committee does not see its way at present to give more than this *interim* report and suggests to the Council to re-appoint the committee.

Dr. Glover assured the Council that the committee had been met in a most kindly manner by the friendly societies.

The report was received and entered on the minutes and the committee re-appointed to continue its work.

The Army Medical Department.

Sir DYCE DUCKWORTH read the following report of the Examination Committee upon the letter of the Director-General of the Army Medical Department with regard to the Council's request for information as to deficiencies in writing, spelling, and composition in the written work of candidates appearing before the examiners of the Department for Commissions in the Army Medical Department.

The Examination Committee of the General Medical Council of Education and Registration beg leave to report to the Council, with reference to the letter of the Director-General of the Army Medical Department (Minutes of Executive Committee, Nov. 22nd, 1897, p. 9), that it may be well to communicate to the Director-General for the information of his office an indication of the aim of the Council in asking him for any information he might be at liberty from time to time to communicate to the Council bearing upon glaringly faulty spelling, writing, or composition in the paper work of any of the candidates for appointments in the Army Medical Department brought under his notice by the examiners by whom these examinations are conducted. The information is desired by the Council not for the identification of candidates but to enable the Council to exercise from time to time a corrective influence upon those bodies from which preliminary examination certificates in general education had been obtained and which had apparently proved remiss in the exercise of their duty in granting certificates to pupils who did not possess a requisite degree of preliminary educational training; and, further, to indicate to the Director-General that the information asked for was afforded by the Director General of the Medical Department of the Navy and by the India Office, and that it had been furnished on former occasions by his predecessor in the Army Medical Department.

The report was received and entered on the minutes and the chairman of the committee was invited to communicate with the Director-General of the Army Medical Department in the sense indicated in the report.

A Delayed Registration.

A report from the Students' Registration Committee having been formally adopted it was agreed, on the motion of Dr. MacAlister, seconded by Dr. Leech, that on the recommendation of the English Branch Council the General Council should register the name of Mr. G. S. Dobrashian, Mem. R. Coll. Surg. Eng., 1880, Lic. Soc. Apoth. Lond., 1881.

Vacancy on the Executive Committee.

Dr. LOMBE ATTHILL was elected a member of the Executive Committee in the place of Dr. William Moore. The election was by ballot and was made from amongst the representatives of Ireland, Sir Philip Smyly, already a member of the committee, excluded.

Claim by Dr. Rentoul.

The next business proceeded with was on the agenda as follows: "The treasurers to make a communication respecting a letter received by the Registrar from Dr. R. R. Rentoul."

Sir DYCE DUCKWORTH read the letter in question. In it Dr. Rentoul wrote: "Respecting my letters of June 14th and July 13th asking the treasurers of the General Medical Council to pay the ten guineas due to me under standing orders, Clause 4, and the treasurers' refusal to pay, will you please bring this before the Council and ask the Council to see that the above rule is put into rightful operation?" At the end of last May session, Sir Dyce Duckworth went on to say, Dr. Rentoul and the other members of committee received payment according to the regulated scale. Dr. Rentoul received the proper, fair, and regulated sum for his attendance, but on the last day of the session he had applied for 10 guineas more because, as he said, the treasurers had mistaken the distance between Liverpool and London. He (Sir Dyce Duckworth) had told Dr. Rentoul that as in years previous they had had a member of Council (Mr. Mitchell Banks) who came from Liverpool and had accepted the payment on the scale on which payment had been made to Dr. Rentoul he did not feel at liberty to pay Dr. Rentoul 10 guineas more. Dr. Rentoul thought he was being badly treated. He wanted to know whether he was to be paid for the Sunday or for his wife who had accompanied him to London. He told the treasurers that if he did not receive the proper sum he would take further steps. Ten days later he (Sir Dyce Duckworth) had received some documents from Liverpool showing that Dr. Rentoul had got the chief constable of Liverpool to measure the distance from his residence to the railway station and had written to the Commissioner of Police of the metropolis to ascertain the distance between Euston Station and the hotel at which he stayed during the sitting of the Council. This, according to the documents in question, had resulted in showing that the distance altogether was over 200 miles and that distance Dr. Rentoul maintained put him into another category than the one the treasurers put him into and entitled him to extra payment. He (Sir Dyce Duckworth) still refused to pay the extra ten guineas and had told Dr. Rentoul that if he thought he had a claim he should refer it to the whole Council, advising him, however, that he (Sir Dyce Duckworth) would not support it. He had heard nothing more until this letter to the Registrar. In consultation with Mr. Bryant it had been determined that they as treasurers were not entitled to pay more than they had already paid. The distance by railway from London to Liverpool was under 200 miles, and the Council were not in the habit of including in calculation of distance the space between the railway stations and the residences or hotels of members. With Mr. Bryant's sanction and approval he laid the matter before the Council.

The CHAIRMAN: Is there any motion to be made on this?

Sir DYCE DUCKWORTH: I have no motion.

Mr. BRUDENELL CARTER said that according to the A.B.C. Time Table the distance between London and Liverpool was 201 miles. He should like to ask their legal adviser if Dr. Rentoul had any legal claim.

Mr. BRYANT said that he and Sir Dyce Duckworth had gone into this matter and they had come to the conclusion that according to the railway Parliamentary fare which was 16*s.* 6*d.* the distance was equal to 198 miles.

Mr. TEALE said this was clearly a case in which unless they were legally bound they were not morally bound to pay. It was not a case in which they could pay for two extra days—one for coming the day before the meeting of the Council and the other for leaving the day after.

The CHAIRMAN: Is there any motion?

Mr. BROWN wished to point out that the question involved here was not so much one of distance between one station and another as it was a question of residence. Dr. Rentoul did not reside in Liverpool but in a suburb of that city and he was clearly entitled to charge as from his residence. When he did that it would be found that he did reside more than 200 miles distant from the Council offices and that being so would it not be better to pay this ten guineas without more to-do? Before making any motion he should like to take Mr. Muir Mackenzie's opinion on the point.

The CHAIRMAN: I do not think it is a matter for Mr. Muir Mackenzie. It is a question for the Council.

Dr. BATTY TUKE: It would be much better to pay the ten guineas and be done with it.

Dr. BRUCE moved that the sum be paid and Dr. BATTY TUKE seconded the motion.

The Council divided, but as 10 voted against and only 9 for the motion was rejected.

Dentists' Registration.

The Council sat in private for considerably over an hour. On the readmission of the public the CHAIRMAN announced

Digitized by Google

that the Council had passed a resolution directing the Registrar not to act on instructions he had already received in the matter of certain registrations in the Dentists Register until further orders from the General Medical Council.

The Dublin Apothecaries' Hall.

Sir DYCE DUCKWORTH moved:—

That all the examinations of the Apothecaries' Hall of Ireland be regularly reported on by an inspector appointed by the Council.

He would drop, he said, the concluding words of the notice he had given—viz., "as well as by the assistant examiners in surgery." He was sorry the motion came on so late in the session as he considered it one of the most important pieces of business the Council had to do. The Council were really responsible for the work that this re-established licensing body might do and it was the Council's duty not only to the public but also to the profession to inspect the work so that they might be fully aware of all that was done.

Mr. BRYANT seconded the motion.

Mr. TICHBORNE, the representative of the Dublin Apothecaries' Hall, said that what the body he represented objected to was turning the assistant examiners into inspectors.

The CHAIRMAN pointed out that the intended references to the examiners had been withdrawn. He asked if Mr. Tichborne objected to the motion in its altered form.

Mr. TICHBORNE: Not in the slightest.

The motion was then adopted.

After some discussion as to whether the assistant examiners in surgery appointed by the Council at the instance of the Privy Council could take notice of examinations in medicine and midwifery as conducted by the Hall,

Mr. MUIR MACKENZIE gave it as his opinion that as, according to the Act of Parliament, it was the duty of the assistant examiners in question to secure such a standard of efficiency as was enjoined by statute, and as for that purpose they should have such powers and perform such duties as the General Medical Council might from time to time prescribe the Council were within their powers to prescribe that assistant examiners who were appointed for the purpose of examining candidates in surgery should have the further power of reporting on the examinations generally.

Mr. TICHBORNE: Would they not in so doing be acting as inspectors?

Mr. MUIR MACKENZIE: No.

On the motion of Dr. MACALISTER, seconded by Sir DYCE DUCKWORTH, it was remitted to the Executive Committee to appoint an inspector for the work suggested in Sir Dyce Duckworth's motion.

The Penal Cases Committee.

Dr. GLOVER moved that the number of members for England on the penal cases committee be increased from three to five.

Mr. BRYANT seconded.

Dr. BRUCE thought it was now too late in the session to interfere with the standing orders and he moved the previous question.

This proposal was at once put to the Council and was carried by 13 votes to 3.

A Further Sitting in Private.

The Council then sat in private to discuss the following notice of motion by Dr. Batty Tuke:—

That it be an instruction to the Penal Cases Committee that no case be laid before the Council except upon evidence which will be presented orally when the case is heard or upon evidence given in the form of statutory declaration.

No intimation of the result of the discussion was given to the public on their re-admission to the Council Hall.

Death Certification.

On the motion of Dr. MACALISTER it was agreed that the following should be entered on the minutes:—

The President informs the Council that owing to the illness and absence of the Right Honourable Henry Chaplin and the absence of Sir Richard T. Thorne on the Continent on official business the deputation on death certification has not yet waited on the President of the Local Government Board, but that a statement to be handed in to the Board has been prepared.

An Invalid Petition.

Dr. MACALISTER moved the adoption of the following report, viz.:—

The Business Committee beg leave to report to the Council as follows: A petition signed by Dr. J. H. Hill and others, entitled "A Petition on the subject of the choice of persons to be Members of the Council by the several Bodies represented thereon," has been examined by the committee. They find that the question to which it refers is one which deals entirely with the legal powers of the medical authorities and therefore does not come within the purview of the Council. The committee accordingly recommend that the petition be not received.

Mr. BRYANT seconded the motion.

Mr. BROWN moved as an amendment:—

That the petition of Dr. J. H. Hill and others be read and entered in the minutes.

He took exception to the statement that the petition was one of a legal character which could not come within the purview of this Council and maintained that the document was in perfect order.

Mr. HORSLEY seconded the amendment.

On a show of hands only two members were found to be supporting the amendment, which was accordingly rejected. The roll was then called and the motion was carried by 9 votes to 2.

Mr. BROWN withdrew his intended motion:

That a deputation not exceeding five persons be received in support of the petition signed by Dr. J. H. Hill and others.

This concluded the business.

Vote of Thanks.

Dr. MACALISTER moved that the Council records its cordial thanks to Sir William Turner for the manner in which he had discharged the arduous duties of chairman during the session.

Sir PHILIP SMYLY seconded and the proposal was carried with applause.

Sir WILLIAM TURNER, in acknowledgement, said that he begged to thank the Council for the hearty vote of thanks they had just passed. He had endeavoured to act, he hoped, fairly to all persons around the Council table. That had been his wish and he thought he might say after the hearty expression of opinion just given that he had not failed.

The Council rose till May next.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed the First Professional Examination for the diploma of Fellow at a meeting of the Board of Examiners:—

Monday, Nov. 15th:

Arthur Stanley Barnes, B.Sc. Lond., Mason College, Birmingham, Herbert Johann Scharlieb, M.R.C.S. Eng., L.R.C.P. Lond., M.B. and B.S. Lond., University College, London; Robert Craig Dun, M.R.C.S. Eng., L.R.C.P. Lond., M.B., C.M., and B.Sc. Edin., Edinburgh, Berlin, and Bern Universities; Harold Collison, Yorkshire College, Leeds; Hugh Lett, Yorkshire College, Leeds, and London Hospital; and David Sydney Graves, Guy's Hospital.

Nine gentlemen were referred back to their professional studies for six months.

Tuesday, Nov. 16th:

Sydney Smith, University College, London, and St. Mungo's College, Glasgow; William Henry Passmore and Burton Alexander Nicol, Charing-cross Hospital; George Aylwin Clarkson, M.R.C.S. Eng., L.R.C.P. Lond., and Charles John Napeau Longridge, St. George's Hospital; and Lewis Augustus Walker, St. Bartholomew's Hospital.

Ten gentlemen were referred back to their professional studies for six months.

Wednesday, Nov. 17th:

Ronald Francis Campbell Ward, B.A. Cantab., Middlesex Hospital; Cyril Alfred Rankin Nitch, St. Thomas's Hospital; John Percy Lockhart Mummery, Cambridge University and St. George's Hospital; Arthur Murray Cudmore, M.R.C.S. Eng., L.R.C.P. Lond., M.B., Ch.B Adel., Adelaide University and London Hospital; and John Ernest Sullivan Frazer, M.R.C.S. Eng., L.R.C.P. Lond., St. Bartholomew's Hospital.

Eleven gentlemen were referred back to their professional studies for six months.

Thursday, Nov. 18th:

Claude Alley Worth, M.R.C.S. Eng., L.R.C.P. Lond., St. Bartholomew's Hospital; Graham Winfield Roll, M.R.C.S. Eng., L.R.C.P. Lond., M.B., B.C. Cantab., Cambridge University and St. Thomas's Hospital; Hormasji Manskji Masind, L.M. & S. Bombay, Grant Medical College, Bombay, St. Bartholomew's and King's College, London; Harold Rothery Nutt, St. Mary's Hospital; and Herbert Dean Pollard, London Hospital.

Eleven gentlemen were referred back to their professional studies for six months.

Friday, Nov. 19th:

Herbert Tilley, M.R.C.S. Eng., L.R.C.P. Lond., M.D., B.S. Lond., University College, London; William Stuart Low, M.R.C.S. Eng.,

Digitized by Google

L.R.C.P. Edin., St. Thomas's Hospital, Edinburgh, and King's College, London; Thomas Patrick Joseph Hartigan, L.R.C.P. & S. Edin., and John Robinson Benson, M.R.C.S. Eng., L.R.C.P. Lond., King's College, London; and James Sherren, London Hospital.

Five gentlemen were referred back to their professional studies for six months. Of the total number, 73, who presented themselves for this examination twenty-seven passed and forty-six were referred.

The following gentlemen having passed the necessary examinations and having conformed to the by-laws and regulations have been admitted Members of the College and are now entitled to practise Medicine, Surgery, and Midwifery:—

Anderson, William Maurice.
Anning, George Paul.
Aubrey, Sydney Ernest.
Baylis, Henry Edward Montgomery
Beath, David Leslie.
Beavis, John Douglas Wilson.
Belt, Francis Victor Owen.
Bell, Robert Hamilton.
Bell, Thomas Herbert.
Bennett, Norman Godfrey.
Bidwell, Charles Hugh.
Black, Charles.
Bottomley, Thomas Abbey.
Boulton, Harold.
Bousfield, Stanley.
Brickwell, Frank.
Chatterton, Edgar.
Chenery, Arthur.
Cholmeley, Montague Adye.
Clark, Reginald William.
Clarke, Frederick Addlerley Howard.
Cole, John William Edward.
Corfield, Edward Carruthers.
Cowburn, Arthur Douglas.
Crossley, Henry Joseph.
Cruddass, Hamilton Maxwell.
Evans, David Edward.
Evans, Frederick Hudson.
Evans, John Howell.
Evans, William.
Falwasser, Arthur Thomas.
Fanning, William Joseph.
Fitz-Hugh, Richard Truman.
Forge, George Baynton.
Foulerton, Harry Percival.
Fremantle, Francis Edward.
Gough, Bernard Bradley.
Greaves, Francis Ley Augustus.
Gregory, Henry Lonsdale.
Grove, Ernest George.
Gutch, John.
Guthrie, Thomas Clement.
Hancock, Arthur Ernest.
Hawkesworth, Thomas Ayscough.
Henshaw, Harry Williams.
Hewitt, Harry Edward.
Hine, Hugh Fitz Neville.
Hornabrook, Rupert Walter.
Hutcheson, George.
Jackson, Harold Hart.
James, Philip William.
Johnson, Alfred.
Johnston, William.
Jones, Edward Shirley.
Jones, Thomas Caldwell Litler.
Joynes, Francis William.
Judd, Walter Rossell.
Leake, Jonas William.
Leclézio, Gustave Ernest.
Littlejohn, Thomas Plested.
Lloyd, Evan.
Lucas, George Humphrey.
McAnally, Edward Arthur.
Mackay, Duncan Matheson.
Macnair, Norman.
Macnamara, Eric Danvers.
Markby, Herbert.
Martin, Francis Raynes.
Maugham, William Somerset.
Maunsell, Debonnaire Frederick.
May, Sydney William.
Mayo, Edmond Godfrey.
Modi, Shapurji Hormasji.
Mossop, Charles Henry.
Nabarro, David Nunes.
Novis, Thomas Shepherd.
Oldfield, Josiah.
Page, Frederick William Tudor.
Palgrave, Edward Francis.
Palser, John Edwin Fo.d.
Pearson, Thomas.
Poole, Cyril Cecil.
Prance, Charles Herbert Gouldsmith.
Prescott, Thomas.
Raper, Henry Edward.
Relph, Herbert John.
Richmond, Richard Thomas.
Rogers, Reginald James.
Roman, Alphonse Henry.
Rowe, William Trethowan.
Scott, John Geddes.
Shea, Henry Francis.
Small, Arthur Atwell.
Smith, Montague.
Smith, Walter Hugh Montgomery.
Starling, Hubert John.
Stevens, Alfred Edward.
Stevenson, Walter Brodie.
Street, Albert Ernest.
Sykes, John Lewis.
Taw, Moung Pha.
Thorneley, Michael Harris.
Trewby, Henry William.
Tyndale, Wentworth Francis.
Tyrrell, Francis Astley Cooper.
Verdon-Roe, Spencer.
Wall, Reginald Cecil Bligh.
Walton, Henry Beckles Call.
Waterhouse, Rupert.
Watt, James George.
Weaver, Frederick Kearsley.
Wells, Lionel Thomas.
White, Frank Harris.
White, Harold Edward.
Wilkinson, Frank Herbert.
Williams, John Daniel Evans.

UNIVERSITY OF LONDON.—At the M.B. Examination in October the following candidates were successful:

First Division.—Cyril Wolrige Alford, Middlesex Hospital; Montague Dixon, B.Sc., University College; Brennan Dyball, St. Thomas's Hospital; John Llewellyn Jones, University College; William Percy Nicol, Mason College; Alfred Walter Sikes, B.Sc., St. Thomas's Hospital; Francis Hugo Thiele, B.Sc., University College; Edwin Josiah Toye, B.Sc., St. Bartholomew's Hospital; and Alexander Gordon Wilson, London Hospital.

Second Division.—Edward William Adams, University College, Sheffield; Louisa Garrett Anderson, London School of Medicine for Women; Walter Rothney Battye, B.Sc., and Charles Henry Benham, University College; Harry Charles Plant Bennett, St. Bartholomew's Hospital; Sidney Herbert Berry, Charing-cross Hospital; John Broadley, Yorkshire College; Harold Wilson Bruce, Guy's Hospital; Alfred Burn, St. Mary's Hospital; Joseph Ernest G. Calverley, St. Bartholomew's Hospital; Colin Campbell Clarkson, University College; Arthur Stanbury Cobbledick, Bristol Medical School; Ernest Coleman, Guy's Hospital; Mary Frances Cornford, Royal Free Hospital; Sydney Cornish, St. Bartholomew's Hospital; Thomas Varley Cunliffe, Owens College and Manchester Royal Infirmary; Wilfrid Arthur Dewhirst, Yorkshire College; Mary Buchan Douie, London School of Medicine for Women and Royal Free Hospital; William Edward Nickolls Dunn, St. Bartholomew's Hospital; Campbell Dykes, University College; Charles Herbert Fagge, Guy's Hospital; Ernest George Leopold Goffe, University College; Charles Poulett Harris, London Hospital; Alice Mary Hawker, London School of Medicine for Women; Cortis Hawsthorne Hodgson, Guy's Hospital; Alfred Lucette Home, St. Thomas's Hospital; George Hutcheson, London Hospital; Arthur Edward Jerman, Westminster Hospital; Beatrice Knowles, London School of Medicine for Women and Royal Free Hospital; Harold Leader and George Kenny Levick, Guy's Hospital; Richard Drummond Maxwell, London Hospital; Robert William Mayston, Guy's Hospital; Charles Herbert Melland, Owens College and Manchester Royal Infirmary; William Tayler Milton, Guy's Hospital; Hugh Percy Noble, Middlesex Hospital; John Hare Phipps, Owens College, Manchester Royal Infirmary, and Guy's Hospital; R. Wynne Cnas. Pierce, B.Sc., St. Thomas's Hospital; G. E. Richmond, B.A., B.Sc., and John Thomas Roberts, Guy's Hospital; Frederick William Robertson, St. Bartholomew's Hospital; Thomas O'Neill Roe, University College; James Percival Scatchard, St. Thomas's Hospital; Joseph Shardlow, University College; Mary Nona Sharman, Royal Free Hospital; Edward Birchall Sherlock, B.Sc. Westminster Hospital; James Eckersley Smith, University College, Liverpool; Lewis Albert Smith, London Hospital; Hubert John Starling, Guy's Hospital; Ernest Stanley Stork, University College; Paul Cuningham Edward Tribe, King's College; William Percival Walker and Richard James Warrington, Owens College and Manchester Royal Infirmary; Bertha Margaret Webb, London School of Medicine for Women and Royal Free Hospital; Percy Glyn S. Williams, University College; and Thomas Harold Woodfield, St. Bartholomew's Hospital.

SIR SQUIRE BANCROFT will give a reading in Plymouth on Jan. 26th in aid of the funds of the South Devon and East Cornwall Hospital.

CHELTENHAM WATER-SUPPLY.—The Cheltenham Town Council at their meeting held on Nov. 22nd decided to apply to the Local Government Board for power to borrow £30,000 for the extension of their waterworks. It is intended ultimately to improve the Tewkesbury station so that it will yield 1,000,000 gallons of water per day.

BRISTOL BOARD OF GUARDIANS AND VACCINATION.—At the meeting of the Bristol Board of Guardians held on Nov. 26th a member, in accordance with notice, moved "That the resolution passed on March 27th authorising vaccination officers to take proceedings against defaulters be rescinded." Unfortunately the resolution was carried by 20 votes to 13.

BORACIC ACID IN BUTTER.—At the meeting of the Cardiff Watch Committee held on Nov. 23rd a deputation representing the Cardiff Grocers Association attended and requested that the Watch Committee should take no steps in prosecuting grocers who sold butter containing boracic acid until it had been ascertained whether it was injurious to health or not. It was decided to await the presentation of a report on the subject by the medical officer of health.

BRISTOL CONVALESCENT HOME.—The Mayor of Bristol announced last week that the subscription list for the convalescent home now exceeds £81,000. He also stated that the committee have resolved that there shall be 80 beds, 65 of which will be apportioned as follows: 30 each to the Royal Infirmary and General Hospital, 1 to the Eye Hospital, 3 to the Bristol Dispensary, and 1 to the Clifton Dispensary.

ROYAL VICTORIA HOME, BRISTOL.—The objects of the institution are to provide a home for the treatment of female inebriates and for presumably reclaimable female offenders as well as to train such of these as are unmarried for domestic service and in various home industries. The committee have been obliged to refuse cases owing to want of funds and therefore appeal to the inhabitants of Bristol for subscriptions.

ROYAL ALBERT HOSPITAL, DEVONPORT.—The annual meeting of this hospital was held on Nov. 22nd, under the presidency of Lieutenant-General Sir W. Forestier-Walker, K.C.B. The annual report showed that 588 in-patients had been admitted during the year and that 2326 casualties had been treated in the out-patient department. The out-patients numbered 523, the great decrease in the number as compared with the preceding year being due to a system of inquiry which had been instituted to ascertain the income of all applicants for gratuitous relief. This had resulted in obtaining from those patients who were willing to pay 2*s.* 6*d.* per month the sum of £13 7*s.* 6*d.* There were 24 patients admitted to the wards for paying patients and their payments amounted to £144. There were 137 women received into the lock wards. The members of the Provident Dispensary numbered 2907 at the close of the year and the working of the Nursing Institute had been most successful. The total cost for maintenance was £4037 or an average cost per bed of £54 4*s.* 10*d.* The treasurer's report showed an adverse balance of £305, against £175 last year. Legacies amounting to £8000 had been left to the institution.

Digitized by Google

THE LATE CYCLONE AT CHITTAGONG.—No country in the world has probably been so terribly tried as India of late. In addition to war, pestilence, famine, and earthquake there has been a serious cyclone at Chittagong which has done immense damage to crops and property and been seriously destructive of life. It is estimated that close upon a million persons have been rendered homeless by it.

MANCHESTER THERAPEUTICAL SOCIETY.—The second meeting of the present session was held on Nov. 24th. Professor Dixon Mann occupied the chair. Dr. E. S. Reynolds opened a discussion upon Thyroid Medication with especial reference to (*a*) indications for thyroid treatment, (*b*) the relative value of the various preparations of thyroid gland, and (*c*) dosage of the crude gland and its preparations. The discussion was continued by Dr. Harris, Dr. Brooke, Professor Dixon Mann, Dr. Wild, and Dr. Coutts.—Dr. E. S. Yonge gave a preliminary communication on Orthoform and its anæsthetic action on the upper air-passages.—Dr. Wild showed a specimen of the Hydrobromide of Emetine and also solutions of the salt of convenient strength as substitutes for the preparations of ipecacuanha.

NEW COTTAGE HOSPITAL AT FRESHFORD, SOMERSET.—For four years Freshford and some of the neighbouring parishes, now comprising a population of about 3000, have had the services of a Queen's Jubilee district nurse. This year in commemoration of the Diamond Jubilee the District Nursing Association has founded, and this month opened, a home for the nurse and at the home has provided four beds and a cot for such cases as cannot be properly treated at their own houses. There is also at the home a bed in a separate room for a private paying case. All medical men practising in the district are *ex officio* members of the association, and the medical director of the home is *ex officio* a member of the executive committee which consists of one or two members from every parish in the nursing district.

THE NATIONAL DENTAL HOSPITAL.—The annual dinner of the past and present students of the above hospital was held at the Holborn Restaurant on Nov. 26th. There was a full attendance, and amongst the guests were Dr. Samuel West, Professor H. R. Spencer, Professor J. Rose Bradford, Dr. Blacker, Mr. Raymond Johnson, Mr. Morton Smale, Mr. J. Smith Turner, Mr. W. B. Paterson, &c. The chair was taken by Mr. E. W. Roughton, F.R.C.S. Eng., the honorary visiting surgeon to the hospital, who, in proposing the toast of the school, mentioned that out of fourteen candidates sent up this year thirteen had been successful in obtaining the Diploma in Dental Surgery at the Royal College of Surgeons of England. During the evening songs were contributed by Mr. Alfred Smith, Mr. W. H. Wheatley, and Mr. Wallis Arthur, whilst ventriloquial sketches by Mr. Fred Russell and sleight-of-hand exhibitions by Dr. Herschell added to the pleasure of the evening.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.—The second meeting of the session was held on Nov. 10th in the Medical Library of University College, Bristol, Dr. J. E. Shaw being in the chair. Dr. Michell Clarke brought forward a case of Filariasis, the patient and specimens being shown. Dr. E. C. Williams showed the following patients who had been treated by the localised application of Super-heated Dry Air: (*a*) Monarticular Rheumatoid Arthritis; and (*b*) Polyarticular Rheumatoid Arthritis. Dr. James Swain made some remarks. Mr. C. A. Morton showed the following specimens: (*a*) a Large Gall-stone successfully removed from the Common Duct of a woman aged seventy-two years; and (*b*) a Renal Calculus detected by means of the X Rays. Dr. James Swain, Mr. Paul Bush, Dr. Skerritt, Mr. Brazier, Dr. Michell Clarke, and Dr. Fisher made remarks on the specimens. Mr. Munro Smith showed a specimen of Tumour in the Mesentery of a Fowl. Dr. F. H. Edgeworth read an interesting paper on Cases of Illness due to Opening of a Sewer. Mr. Munro Smith, Mr. Paul Bush, Mr. H. Wathen, Dr. D. S. Davies, Dr. Rogers, Dr. Harrison, and Mr. J. C. Heaven commented on the paper. Mr. Munro Smith read a paper on a Case of Cancrum Auris. Dr. Fisher, Mr. E. Harris, and Dr. D. S. Davies spoke on the subject. Dr. J. O. Symes gave a demonstration of Widal's Serum Diagnosis of Enteric Fever. Dr. Davies, Dr. Rogers, and Mr. H. Wathen made remarks.

VACCINATION AWARD.—The Local Government Board has awarded to the representatives of the late Mr. Peter Swales, of Sheerness, the proportion of the grant for successful vaccination to which he was entitled at the time of his death. This is the twelfth award made to Mr. Swales, who thereby attained the maximum possible for his service of twenty-five years and four months as he had not been twelve months appointed when the first inspection was made. Mr. Swales, who qualified as M.R.C.S. Eng. in 1861 and died in February, 1896, held several appointments in his locality including that of medical officer of health of Queenborough.

SUPERANNUATION OF A MEDICAL OFFICER.—At the meeting of the Downham Market board of guardians held on Nov. 19th it was decided to grant a superannuation allowance of £60 12*s.* per annum to Dr. Alexander J. Mackintosh, medical officer and public vaccinator to the third district of Downham union. Dr. Mackintosh has passed thirty-seven years in the service of this union and has had the unusual good fortune to receive the Government grant for successful vaccination from its commencement with the exception of one year when he allowed an assistant to vaccinate only three cases. He graduated as M.D. at Glasgow University in 1858 and is the author of numerous articles quoted in Taylor's "Principles of Medical Jurisprudence."

INFIRMARY MEDICAL SUPERINTENDENTS' SOCIETY. The November meeting was held on Nov. 27th, at the Poplar and Stepney Sick Asylum, Mr. Charles Spurrell, the medical superintendent, being in the chair. The society unanimously agreed to Mr. Walter Burney's motion to subscribe one guinea annually to the Royal Medical Benevolent College. The wards of the hospital were visited and Mr. Spurrell showed the following cases: (1) Locomotor Ataxia with Charcot's Disease of the Knee-joint; (2) Laryngeal Gumma for which tracheotomy had been performed; (3) Floating Kidney; (4) Osteitis Deformans; (5) Peripheral Neuritis of the Lower Limbs with Paralysis of the Left Third Nerve in a phthisical woman; (6) Tuberculous Arthritis of the Elbow and Wrist in a boy; and (7) case of Ascites with great Dilatation of the Superficial Abdominal and Thoracic Veins in a young man whose history revealed no proof of alcoholism.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—A meeting of this society was held at 20, Hanover-square on Nov. 24th, Dr. J. F. Payne, President, being in the chair. Dr. Payne showed a case of Sarcoma of the Skin in a man about sixty years of age. He was the subject of a general dry eczema. Over the right pectoral region there was a well-marked, raised, ulcerating tumour rather larger than a five-shilling piece which had existed for three years and between the shoulders was a second tumour about the size of a walnut; this was much more raised than the anterior tumour and the surface was but little ulcerated. Histologically the malignant elements showed as spindle-celled sarcomatous tissue.—Mr. Hope Grant showed for Dr. Abraham a case of Xanthoma Diabeticorum in a robust middle-aged man whose urine when examined had never contained more than a trace of sugar. At the October meeting in a similar case shown by Dr. Abraham there was found a large quantity of sugar. There were a number of well-marked yellow-tipped nodules about the flexor surfaces of the forearms; the nodules were discrete but grouped. They were also plentifully arranged on both surfaces of the knees and lower thighs. There were a few scattered nodules over the back and abdomen. Dr. Payne remarked that at the Dermatological Congress it was stated that the histology of these cases was not that of xanthoma.—Dr. Walsh showed a case of Infective Angeioma. The case had been published and named by Mr. Hutchinson some two years ago. The patient was a fairly healthy looking girl, aged twenty-one years, and the condition had commenced when she was about thirteen years of age. It began on one arm near the wrist and gradually spread in arborescent lines until it had affected a large portion of the whole surface of the body. Where it had travelled faint cicatrices had been left. The term "infective" was used only in a limited sense to imply that it spread locally.—Dr. Savill showed two patients, one suffering from Lupus of the Conjunctiva with many recurrent multiple nodules upon the face and the other being a case of localised Scleroderma with large morphœa patches on the chest and abdomen.

THE LIEUTENANT-GOVERNOR OF BRITISH COLUMBIA.—The very responsible office of Lieutenant-Governor of British Columbia has been entrusted to Dr. T. R McInnes who holds the qualification of M.D. Harvard and is a Member of the College of Physicians and Surgeons of Ontario. Dr. McInnes was born in Nova Scotia of Scotch parents. In 1878 he entered the Dominion House of Commons and obtained a seat in the Senate three years later. In the same year he was appointed Medical Superintendent of the British Columbia Lunatic Asylum.

LITERARY INTELLIGENCE.—Messrs. Baillière, Tindall, and Cox inform us that a second edition of Sir William Broadbent's work on Heart Disease is being printed, the first edition having been sold out.—The addresses of thanks to the Czar and to the President and Committee of the Twelfth International Congress, signed by 100 British members, have been forwarded this week. They were both tastefully illuminated by Messrs. Marcus Ward and Co., the one being in the form of a very handsome book bearing the Russian arms on the cover and the other a scroll enclosed in a scarlet morocco leather case.

UNIVERSITY OF CAMBRIDGE.—The Examiners in State Medicine for the year 1898 are Dr. B. Anningson, Dr. W. Collingridge, Professor A. A. Kanthack, Dr. J. L. Notter, and Dr. T. Stevenson.—The appointment to the Professorship of Surgery, vacant by the death of the late Sir G. M. Humphry, is to be further suspended until April 18th, 1898, the General Board of Studies being not yet in a position to make definite proposals as to the stipend, duties, &c., of the chair.—Mr. J. W. W. Stephens, B.A., M.B., B C. (Caius and Gonville), has been elected John Lucas Walker Student in Pathology, vice Mr. L. Cobbett, M.A., M.B. (Trinity), and Mr. H. K. Wright, M.D., C.M., McGill University, Montreal, has been awarded an exhibition of the value of £50 from the John Lucas Walker Fund. The following degrees in Medicine and Surgery were conferred on Nov. 25th:—Doctor of Medicine: L. B. Hayne, B.A., and H. M. Stewart, M.A. Bachelor of Medicine and Bachelor of Surgery: G. T. Watson, B.A., and T. L. Jackson, B.A.

DIPHTHERIA IN LONDON.—The amount of fatal diphtheria registered in London during the week ending Nov. 20th showed further decrease on former weeks. The deaths registered from the disease during the week numbered 37, as against 65, 59, and 46 in the three weeks preceding, and as against the corrected decennial average of 48 for the corresponding week of the period 1887-96. All the 37 deaths were of persons aged from one to twenty years, and 4 belonged to Lewisham, and 3 each to St. Marylebone, St. Pancras, Bethnal Green, Wandsworth, and Camberwell sanitary areas. On Nov. 20th there were 1064 patients in hospital on account of diphtheria, the admissions during the week having been 150. In the outer ring the registered deaths numbered 11, of which 5 occurred in West Ham, and 3 in Edmonton registration districts. Last week witnessed a large rise in the number of fatal attacks from diphtheria in the county of London, the registered deaths having been as many as 63 and 13 in excess of the corrected decennial average for the corresponding week of the period 1887-96. The fatal cases were widely scattered over the metropolis though as usual certain defined areas suffered more than others. Thus 6 deaths belonged to Lambeth, 5 to Battersea, 4 each to St. Pancras, Islington, Hackney, and Wandsworth, and 3 each to Paddington, Kensington, Bethnal-green, Newington, and Bermondsey sanitary areas. Of the 63 deaths 3 were of infants and 2 of persons aged over twenty years, whilst 44 were of young children aged from one to five years. On Saturday 1052 persons were under isolation in London hospitals on account of diphtheria, the fresh admissions during the week having numbered 158. In the outer ring there were 14 deaths registered from the disease, of which 5 were in the endemically affected West Ham registration district. The vast Edmonton Union was entirely free from registered fatal diphtheria. Thus in a population estimated at 6,291,677 persons there were last week 77 deaths registered from this disease out of 97 in the 33 towns of the Registrar-General (including London) with their 11,000,000 inhabitants.

ROYAL UNITED HOSPITAL, BATH.—The Amateur Theatrical Week at the Theatre Royal, Bath, has been very successful and the final performance was received with great enthusiasm by a crowded audience. At the conclusion of the *Mikado* the Rev. E. Handley, President of the Royal United Hospital, which receives the proceeds, came before the footlights and addressing the Mayor expressed his gratification at the fact that aid was given to the hospital in this way rather than by the former plan of street collections in one Saturday in the year. Dr. Lionel Weatherly, the organiser of the performances, afterwards made a speech which was very well received.

PRESENTATIONS TO MEDICAL MEN.—On Nov. 12th at a farewell entertainment at the Thistle Hotel, Milnathort, Mr. E. N. Burnett, M.B. Glasg., who has relinquished his practice in that town, was presented with a gold albert chain subscribed for by the inhabitants generally.—On Nov. 17th Mr. T. T. Somerville, L.R.C.S. Irel., of Sheffield, was the recipient from the members and supporters of the Sheaf Works Ambulance Class of a silver-mounted walking-stick and umbrella suitably inscribed in recognition of his services in preparing the class for examination on First Aid.—On Nov. 19th Mr. H. F. Cook, L.R.C.P. Lond., M.R.C.S. Eng., was presented at a meeting at the National Schools, Treeton, with an illustrated address and a purse of sovereigns from the inhabitants of Treeton, Catcliffe, Winston, Aughton and Ulley on the occasion of his leaving Treeton for Australia. Mr. Cook had been an assistant medical officer of the district for upwards of two years and his unvaried kindness and courtesy were appreciated by all.—At the Public Hall, Clevedon, Somersetshire, on Nov. 20th, after the completion of a course of lectures which have been recently held in connexion with the St. John Ambulance Classes the lecturer, Mr. H. Rogers-Tillstone, M.D. Aberd., was presented with a handsomely fitted "emergency bag" and a mother-of-pearl match-box together with an address containing a list of subscribers in appreciation of the lectures given by him.—Mr. C. M. Maxwell, of Lasswade, who has unfortunately been compelled to relinquish practice there on account of ill-health, has been presented by his patients with £200 and a silver salver to carry an inscription; the miners of Whitehill Colliery, to which he is medical officer, have also arranged to give him two silver dessert dishes. Dr. Maxwell has made many friends in Lasswade, a picturesque locality not far from Edinburgh, where he has been in practice for nearly seventeen years. He now intends to proceed to Australia in the hope that the change of climate may be beneficial.

Northern Central (2.30 P.M.), West London (2.30 P.M.).

SATURDAY (11th).—Royal Free (9 A.M. and 2 P.M.), Middlesex, (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

TUESDAY (7th).—PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Prof. Rose Bradford: Experimental Atrophy of the Kidney.—Mr. S. G. Shattock: Negative Action of Sewer Air in raising the Toxicity of Non-virulent Diphtheria Bacilli.—Mr. H. C. Haslam: A Note on the Morphology of the Colon Bacillus.—Mr. Strangeways Pigg: Four Unusual Cases of Melanotic Sarcoma.—Mr. F. C. Abbott: Congenital Abnormality of the Sternum and Diaphragm with Downward Displacement of the Heart.—Mr. Parkes Weber: A Heart with Extreme Calcification of the Aortic and Mitral Orifices from a Case which presented exceptional Physical Signs.—Dr. F. W. Andrewes and Mr. James Berry: Nose and Lung from a case of Glanders (Human).—Prof. McFadyean: Lung from a Case of Glanders (Horse).

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (40, Leicester-square, W.C.).—8 P.M. Paper:—Mr. C. Tomes: Partial Suppression of Teeth in a very Hairy Monkey (Colobus Caudatus). Communications:—Mr. R. Barrett: A Case of Composite Odontome in the Lower Jaw.—Mr. G. Thomson: Chloroform in Dental Surgery.—Mr. H. Ll. Williams: Excision of Necrosed Roots.

ROENTGEN SOCIETY (Medical Society's Rooms, 11, Chandos-st., W.).—8.30 P.M. Paper:—Mr. A. C. Swinton: Adjustable X-Ray Tubes.

WEDNESDAY (8th).—HUNTERIAN SOCIETY (London Institution, Finsbury-circus, E.C.).—8 30 P.M. Clinical Evening. Cases will be shown by Dr. A. T. Davies, Dr. Appleford, Dr. Kelson and Dr. G. H. Sequeira.

MEDICAL SOCIETY OF UNIVERSITY COLLEGE (London).—8 30 P.M. Mr. A. Pearce Gould: University College Hospital Thirty Years Ago.

LARYNGOLOGICAL SOCIETY OF LONDON (20, Hanover-square, W.).—5 P.M. Cases and Specimens will be shown by Dr. J. Horne, Dr. Pegler, Mr. W. Wingrave, Mr. de Santi, Dr. Bond, Dr. S. Spicer, Dr. H. L. Lack.

THURSDAY (9th).—OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11, Chandos-street, Cavendish-sq., W.).—8 P.M. Patients and Card Specimens. Cases will be shown by Mr. W. J. Cant, Mr. Hartridge, Mr. Holmes Spicer, Mr. Stanford Morton, Mr. Lawford, and others.

HARVEIAN SOCIETY.—8.30 P.M. Mr. Juler: The Syphilitic Diseases of the Eye and its Appendages. (Harveian Lecture.)

BRITISH GYNÆCOLOGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M. Specimens will be shown by Mr. O'Callaghan. Papers:—Dr. J. A. Shaw-Mackenzie: Hæmorrhagic Endometritis.—On the Dangers to the Ureters in performing Hysterectomy.

FRIDAY (10th).—CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8.30 P.M. Paper:—Mr. A. Pearce Gould: A Case of Acute Intestinal Obstruction relieved by Operation, Death from Intestinal Toxæmia on the Ninth Day after Operation.—Mr. C. B. Lockwood: A Case of Radical Cure of Inguinal Hernia. Injury to the Bladder, Formation of Phosphatic Calculi, Lithotrity, Recovery.—Mr. A. E. Barker: Fifteen Consecutive Cases of Acute Intussusception.

LECTURES, ADDRESSES, DEMONSTRATIONS, ETC.

TUESDAY (7th).—NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3.30 P.M. Mr. Ballance: Surgery of the Nervous System.

HOSPITAL FOR NERVOUS DISEASES (73, Welbeck-street).—4.30 P.M. Dr. Fletcher Beach: On Cases of Epilepsy and other Convulsive Disorders of the Nervous System.

WEDNESDAY (8th).—HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. H. Mackenzie: Mitral Stenosis.

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Dr. D. Hood: Albuminuria.

THURSDAY (9th).—THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Dr. Colman: Demonstration of Selected Cases.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

THE WATER-SUPPLY OF ROME.

To the Editors of THE LANCET.

SIRS,—Your correspondent, Dr. Wyckoff, to whom you replied in THE LANCET of Nov. 6th, page 1231, had probably in his mind the opening on Sept. 10th, 1870, of the Acqua Marcia, which, though the hardest of the four chief supplies, is looked on as the best, being the coldest of all the thirteen sources. The Acqua Paola is the softest and the Vergine the most aerated, the Felice being, save in its higher temperature, almost identical with the Marcia. Pope Sextus V. and his engineer, Pompilio Eusebi, of Perugia, included the Marcia in their scheme for the re-opening of the ancient aqueducts, which received the Papal approval in 1589, but the death of the Pope intervening the commissioners dropped it and confined their operations to the other three. But excellent as are these waters there were until recently at any rate a number of shallow wells in use, of which Dr. Francisco Marino-Zuco and Dr. Guido Fabris declared in 1885, "La composizione chimica di queste acque, adattatissima alla coltura dei germi viventi, e *le loro posizione molto prossima alle fognature*, da cui possono ricevere le putride infiltrazioni e i germi morbigeni, i quali trovebbero in esse liquidi fertili per la loro propagazione, ci fanno concludere che *l'uso delle dette acque non è soltanto nocivo a chi ne beve, ma è altresì molto pericoloso per la salute pubblica*, e percio nello interesse della pubblica igiene *deve essere rigorosamente proscritto*." If the municipality from whose "Bulletino" I have taken this extract have carried out the earnest recommendation of their own official chemical advisers and closed the city wells there certainly has been "an improvement in the water-supply" such as Dr. Wyckoff inquires about and that within the last dozen years.

I am, Sirs, yours faithfully,

Nov. 29th, 1897. M.D

"WANTED SUGGESTIONS FOR TREATING A GANGRENOUS ULCER."

To the Editors of THE LANCET.

SIRS,—In reply to a letter in THE LANCET of Nov. 27th from Mr. John D. Rice asking for suggestions for the treatment of gangrenous ulcers I would recommend him to try pulvis cinchonæ dusted over the ulcer night and morning with complete rest in bed. This treatment was, I believe, suggested by Dr. Sidney Ringer in his book on Therapeutics some years ago. I have frequently found it succeed when all other treatment has failed. The following case which I now have under my care illustrates this method of treatment. A woman, aged seventy-five years, about two months ago fell down and grazed her right shin. She treated herself for two weeks with poultices and warm fomentations. When I first saw her she had a large, acutely painful gangrenous ulcer about 3 in. by 4 in. in size. The edges were undetermined and the surrounding skin was inflamed and boggy with several large bullæ filled with dark blood-stained serum. The surface of the ulcer was very irregular, varying in depth from an eighth to a quarter of an inch, completely destroying the subcutaneous tissue and involving the muscular layer. The ulcer was partly covered with black sloughs and the discharge was abundant and offensive. All loose sloughs were removed and the ulcer was bathed with boracic lotion and carefully dried and then well dusted with powdered cinchona bark; the wound was covered with linen rag, the limb enveloped in cotton-wool and elevated on pillows. The dressing was changed night and morning and the wound well washed with boracic lotion and powdered on each occasion. The powder has a tendency to "cake" and such crusts require carefully removing every third day. Under this treatment the ulcer rapidly decreased in area and depth, the remaining sloughs dropped off, and healthy granulations made their appearance. The discharge lessened and was no longer offensive. The pain ceased and the surrounding skin became firm and healthy. The progress towards recovery has been continuous and at the date of writing the wound has practically ceased to exist. I should be glad if any gentlemen who have adopted this treatment would communicate results.—I am, Sirs, yours faithfully,

EDWARD MONRO SPOONER, M.D. St. And.

Blandford, Dorset, Nov. 29th, 1897.

A Sufferer.—The abuse is rife all over the kingdom. If our correspondent will send a statement on the matter to us (in the signature of which other medical men in the neighbourhood should join) we will consider the desirability of its publication.

CHEMICAL NOMENCLATURE.

SOME change must soon be made in chemical nomenclature or a large portion of a lecture on chemistry will be occupied in articulating the name of the subject which it is proposed to discuss. In a late number of the *Comptes Rendus* MM. A. Haller and A. Guyot describe a new substance they have obtained which has the portentous title of the "tétramethyldiamidodiphenyldianthranoltetramethylédiamidé symmetrical with the corresponcent oxanthranol." This, we think, would be hard to beat even amongst German sesquipedalian words. The chemists want a Linnæus.

F. H.—We doubt if any good would be done by pointing out the childish and mischievous absurdities of a quack's circular in our columns. All readers of THE LANCET know that such literature is stuffed with lies aimed at the credulity and the purse of the unfortunate public. We recommend our correspondent to enclose the circular to the Parliamentary representative of his electoral division and to ask whether in the near future such frauds cannot be stopped by legislation.

BIRTHS AND DEATHS IN LONDON.

To the Editors of THE LANCET.

SIRS,—Will you kindly inform me how to obtain the register of births and deaths in London this year, 1897?—I am, Sirs, yours truly,

Sheerness, Nov. 23rd, 1897. L.R.C.P.

*** The figures for the last quarter of 1897 obviously cannot be given; for the three completed quarters of the year the figures are appended.—ED. L.

1897.	Births.	Deaths.
First quarter	34,643	20,504
Second quarter	32,412	17,261
Third quarter	33,722	21,560
Three quarters	100,777	59,325

Mr. T. Hebb.—Our correspondent would not be justified in recommending the treatment or using it under cover of another name or method. He can only try to wean the persons concerned from the error of their ways.

THE ETHICS OF DEATH CERTIFICATION.

To the Editors of THE LANCET.

SIRS,—I should be glad of the opinion of your readers on a point of conduct which has given me some qualms. Some time since I was called to see a child of eight years who after the ordinary evening meal, composed of a milk pudding of some kind, became violently sick and brought up a considerable quantity of blood. There was severe diarrhœa and the temperature shortly ran up to 104° F. I must confess that I was at a loss to explain these symptoms except on the assumption that the child had swallowed an irritant poison or had taken a sharp fragment with the food. A neighbouring practitioner was called in to assist me but neither he nor any one of the others who were called in consultation could throw any light on the nature of the illness. Ultimately the child became delirious and died within three days. From every point of view I should have liked a post-mortem examination but to this the parents demurred. Convinced as I was and am that death was due to natural causes I, after some hesitation, certified that death was due to gastritis, an accurate diagnosis no doubt but under the circumstances somewhat misleading. I wish to know whether my conduct commends itself to my fellow practitioners, or whether I ought to have offered the bereaved parents the alternative of a post-mortem examination or an inquest on the ground that I was unable to certify that whereof I was admittedly ignorant. An expression of opinion on this subject may serve as a guide not only to me but to other practitioners who happen to find themselves landed in a similar dilemma. I am, Sirs, yours faithfully,

Nov. 29th, 1897. INTIMIDAD.

Ignoramus is recommended to follow the custom of the place, to be ascertained by inquiring from one of the resident medical men.

"A TESTIMONIAL TO DR. JOHN T. ARLIDGE."

To the Editors of THE LANCET.

SIRS,—Will you kindly oblige by inserting in THE LANCET the subjoined additional subscriptions to the testimonial for Dr. J. T. Arlidge, Mr. W. H. Folker, F.R.C.S. Eng., of Hanley, has kindly undertaken to receive subscriptions locally. Sir Thomas Wardle, President of the Silk Association of Great Britain and Ireland, has also kindly joined the committee. I am, Sirs, yours truly,

CHAS. F. MOORE.

10, Upper Merrion-street, Dublin, Nov. 30th, 1897.

	£	s.	d.		£	s.	d.
Mr. J. H. Tylecote, M.D. St. And....	0	10	6	Mr. Jas. Holmes, M.D. Edin.	0	10	6

				Mr. George Menzies ...	1	1	0

A Disgusted M.D. is recommended to bring the matter before the General Medical Council. In doing so he will be careful to enclose copies of both papers and he would be well advised to secure the coöperation of other practitioners in the neighbourhood.

"A BOOK ON STAMMERING."

To the Editors of THE LANCET.

SIRS,—I note on p. 1433 of THE LANCET of Nov. 27th a request to vindicate a small book on "Stammering," &c. I have put forth a booklet on the subject entitled "Lip Chorea," published by Bale, 85, Great Titchfield-street, W., at 1s. net.—I am, Sirs, yours faithfully,

64, Seymour-street, W.. Nov. 27th, 1897. EDWARD BLAKE.

To the Editors of THE LANCET.

SIRS,—The little book on Stammering—constantly advertised in your columns—by the late Emil Behnke, and edited by his widow, answers all purposes, being free from the faults of most of such essays and founded on that sound knowledge of physiology which is essential to the successful and permanent treatment of all defects of speech.

I am, Sirs, yours faithfully,

Nov. 29th, 1897. ELLBEE.

*** Mr. G. Phillips and Mr. J. F. Hallows also wish to call the attention of "W. R. K." to the late Emil Behnke's book.—ED. L.

Mr. N. Evedin.—It is within the discretion of the coroner to call either medical witness or both.

A REMEDY FOR SEVERE LUMBAGO.

To the Editors of THE LANCET.

SIRS,—In answer to "L.R.C.P.," who asked in THE LANCET of Nov. 13th for a remedy for lumbago, I may state that I have had good results with ammonii chloridum (gr. xx.) combined with ammonii carbonas (gr. v.), or a mixture: ammonii chloridi 3iii., liquoris hydrargyri perchloridi ℥xs., spiritus chloroformi ℥ss., infusum gentianæ compositum ad ℥vi.; ℥ss. ter in die ex aqua.

I am, Sirs, yours faithfully,

R. STUART BENNIE, M.A., M.B., C.M.

Dobeross, Saddleworth, Yorkshire, Nov. 18th, 1897.

A STORY OF MORALS.

To the Editors of "THE LANCET."

SIRS,—I make no comment on the following case which I have fully investigated and every fact of which I can prove and have proved in conjunction with a colleague. A child of eleven years was suffering from a purulent vaginal discharge which proved to be gonorrhœa. On investigation it was discovered that this child had contracted it from her uncle; she had given it to her brother aged seven years, who in turn had passed it on to his sister aged three years. The boy of seven years had a very bad attack with phimosis and the girl of three years had it somewhat severely. On further investigation the following side-lights were discovered. The girl of eleven years felt no discomfort through connexion with an adult man of about thirty years; rather the contrary. She gives a graphic and evidently truthful account of her seduction, at the age of eight years, by a boy four years her senior, since which time she has been living in frequent sexual intercourse with boys. The mother of this child three years ago gave the father syphilis and was turned out of doors, since which time she has not been back and is believed to be living the life of a common prostitute. The uncle was confronted with the girl who accused him of having given her gonorrhœa and on being pressed confessed in the presence of the girl's father and the husband of his own sister that it was true and that he had done it to get rid of his own disease, having succeeded in doing so in this way on four other occasions. Meanwhile the girl's father and the other man, who were present when the remark was made, stood placid and indifferent, expressing neither indignation, disgust, nor surprise.

I am, Sirs, yours faithfully,

Dec. 1st, 1897. M.R.C.S.

Spectator brings to our notice a matter to which we have given attention before. The publisher distributes books to the press, and is therefore indirectly responsible for the publicity given to medical authors in a lay paper.

THE TITLE OF DOCTOR.

To the Editors of THE LANCET.

SIRS,—I should be much obliged if you will kindly give your opinion as to whether a graduate of a university, say M.B., B.S., or M.B., C.M., has the right to use the word "Surgeon." Graduates are very jealous if a simple diplomate uses the word "Doctor."

I am, Sirs, yours faithfully,

Nov. 30th, 1897. ENQUIRER.

*** A Bachelor of Surgery is a *surgeon* by right; a Bachelor of Medicine has been styled a *doctor* by courtesy and long-established custom, probably because the gap between his position and the position of Doctor of Medicine has been very small, although the modern tendency is to widen it. A diplomate of a corporation cannot make his *membership* or *license* carry the title of *Doctor*. The trouble arises, as we have so often pointed out, from the fact that the public use as a popular title for a medical man the academic title which happens to pertain to one group of medical men.—ED. L.

Rus.—The matter is one for the Council's discretion. The last superintendent of an asylum under the Council's jurisdiction who resigned his office received a pension, which would seem to indicate the Council's views.

R. R.—THE LANCET, vol. i., 1896, contains several papers on the subject.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received: *Heywood Advertiser, Birmingham Gazette, Bradford Observer, Accrington Observer, Newbury Weekly News, Preston Guardian, Carlisle Journal, Kentish Express, Times of India, Pioneer Mail, Cambridge Express, Halifax Guardian, East Anglian Daily Times, Western Morning News, Glasgow Herald, Architect, Dundee Advertiser, Manchester Courier, Builder, Yorkshire Post, Sheffield Telegraph, Sussex Daily News, Grantham Journal, Halifax Guardian, Norfolk Chronicle, Liverpool Daily Post, Kidderminster Shuttle, Derbyshire Times, Newport Advertiser, Northampton Mercury, Kendal Mercury, Leicester Post, Bristol Mercury, Lowestoft Standard, Keighley News, Doncaster Chronicle, Cheltenham Mercury, North Wilts Herald, Grimsby News, Essex County Chronicle, Somerset County Gazette, Worcester Chronicle, Freeman's Exmouth Journal, Sanitary Record, Lisburn Standard, Brighton Gazette, Mining Journal, Hertfordshire Mercury, Local Government Chronicle, Reading Mercury, City Press, Newbury Weekly News, Weekly Free Press and Aberdeen Journal, Local Government Journal, Surrey Advertiser, Australasian Medical Gazette, Townsville Daily Bulletin, Keighley Herald, Jarrow Guardian, Carnarvon Herald, Leeds Mercury, West Middlesex Herald, Clifton Chronicle, Pullen's Kent Argus, Radcliffe Express, &c., &c.*

Christmas Presents

FOR

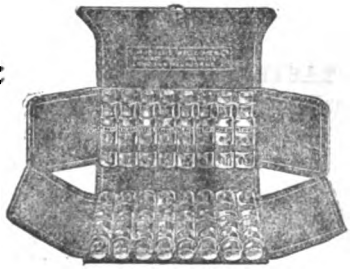
MEDICAL MEN.

TRADE MARK **'Tabloid'** BRAND

Medicine & Hypodermic Cases

No. 16.

'TABLOID' MEDICINE CASE.



In black or olive green Levant morocco. Outside measurements, 8½ × 3¾ × 1¾ in. Contains eight ½-oz. and six 1-dr. vials fitted with 'Tabloid' Compressed Drugs, from **19/-**.

Also supplied in "natural" tint crocodile.

SILVER HYPODERMIC 'TABLOID' CASE.

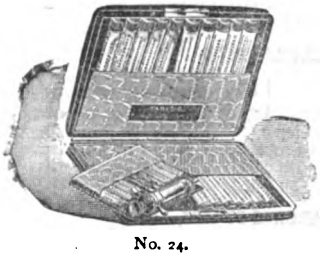
Solid silver, gilt lined. Fitted complete with solid silver syringe, platino-iridium needles, fourteen tubes of 'Tabloid' Hypodermic Drugs, etc., **£10 10s.**

No. 17.

'TABLOID' MEDICINE CASE.

In calf. Outside measurement, 7 × 3½ × 2 in. Contains sixteen ½-oz. vials fitted with 'Tabloid' Compressed Drugs, from **22/-**.

Also supplied in cow hide from **24/-**, and in olive green Levant morocco from **23/-** each.



No. 7.

'TABLOID' HYPODERMIC POCKET CASES.

Nos. 7 and 21	**12/6**;	No. 30,	**14/-** each
do. in brown or green seal	**18/-**;	,,	**19/-** ,,
do. in crushed morocco	**19/-**;	,,	**20/-** ,,
do. in brown or green crocodile	**20/-**;	,,	**21/-** ,,

No. 30.

No. 24.

'TABLOID' EMERGENCY CASE.

A complete 'tabloid' equipment of hypodermic and other drugs suitable for emergencies, hypodermic syringe, etc., **24/-** each.

In brown or green seal .. .. **32/-** each

,, ,, crocodile .. **40/-** ,,

In addition to those illustrated above, the following will be found handsome cases for presentation. All are fitted with 'Tabloid' Compressed Drugs, and, in the Hypodermic Cases, syringes, needles, and other accessories are included. Further illustrations and particulars will be sent on request. Special designs are made to order.

'TABLOID' MEDICINE CASES.

No. 16A.—In Black Morocco... ...	from	13/- each
,, In Olive-green Levant Morocco ,,		18/- ,,
,, In Brown Seal ... ... ,,		21/- ,,
No. 23.—POCKET CASE ... ... ,,		9/- ,,
,, In Brown or Green Crocodile ..		20/- ,,
'TABLOID' OPHTHALMIC CASE ...		7/6 ,,
In Aluminium		14/- ,,
In Brown Crocodile ...		12/- ,,
In Brown Seal		10/- ,,

PHYSICIANS' CYCLE HANDLE-BAR 'TABLOID' MEDICINE CASE ...	from	33/- each
PHYSICIANS' CYCLE STAY-BAR 'TABLOID' MEDICINE CASE ... ... ,,		40/- ,,
DENTAL HYPODERMIC 'TABLOID' CASE		21/- ,,
In Black Morocco		25/- ,,
In Brown Seal		29/- ,,
In Brown or Green Crocodile		30/- ,,

Schieffelin's

AT POPULAR PRICES.

PERFECT

NOT AFFECTED BY CLIMATE.

Our Pills are coated while soft, and are not injured by heat at any stage of the process of manufacture, so that vegetable or organic matters are not charred, nor are volatile principles lost.

In TASTELESS, TRANSPARENT COATING. Solubility Unequalled, solution taking place in a few minutes; whilst, owing to its Transparency, the colour of the pill mass can be easily seen.

PILLS

Selected from our List of over 400 useful Formulæ :—

No. 30 **ALOIN COMP**

Aloin,	1-8 gr.
Resinæ Podophylli,	1-8 gr.
Ext. Belladonnæ Fol.,	¼ gr.

No. 33 **ALOIN, STRYCHNIÆ, ET BELLADONNÆ, 2nd Form**

Aloin,	1-6 gr.
Strychniæ,	1-60 gr.
Ext. Belladonnæ,	1-8 gr.

This pill is recommended in Chronic Constipation—the Aloin for its laxative effect, the Strychnia to relieve spasm of the intestines, and the Belladonna because of its paralysing influence upon the inhibitory intestinal nerves.

No. 36 **ALTERATIVE**

Ext. Coloc. Comp.,	1½ gr.
Pulv. Rhei,	1½ gr.
Mas. Hydrarg.,	1 gr.
Ol. Carui,	1-40 gtt.

These pills have proved of great service in sluggish states of the liver with constipation, as they act without shock or depression to the system, being gentle, yet effective.

No. 47 **ARSENI IODIDI**, 1-20 gr.

No. 48 **ARSENI SULPHIDI**, 1-100 gr.

No. 49 **ARSENI SULPHIDI**, 1-50 gr.

No. 50 **ARSENI SULPHIDI**, 1-30 gr.

Dr. McLaughlin (Am. Med. Ass'n) finds Sulphide of Arsenic to be tolerated by the stomach better than arsenic in other forms. He gives it in the crude form (Realgar, As_2S_2) in granules of 1-100 grain (0·0009 gramme) "ordered from Schieffelin & Co., of New York."

No. 466 **EMMENAGOGUE (Improved)**

Ext. Ergotæ,	1 gr.
Ext. Gossypii,	1 gr.
Pulv. Aloes Socot.,	1 gr.
Ferri. Sulph. Exsic.,	1 gr.
Ol. Sabinæ,	½ gr.

No. 136 **ERGOTIN** (Ext. Ergotæ), 3 gr.

The demand for "Ergotin" Pills has been very great. We have manufactured for a long time this "Ergotin," which is, more properly speaking, a carefully prepared aqueous extract. The "Ergotin" of the market is of several kinds and generally unreliable. Our 3-gr. pill represents 15 to 17 grains of Ergot.

No. 137 **ERGOTIN COMP.**

Ext. Ergotæ,	3 gr.
Ext. Cannab. Ind.,	1-6 gr.
Strychniæ,	1-60 gr.

No. 209 **FERRUGINOUS (Blaud's)**

Ferri Sulph.,	1½ gr.
Potassii Carb.,	1½ gr. (A)

No. 210 **FERRUGINOUS (Blaud's)**

Ferri Sulph.,	2½ gr.
Potassii Carb.,	2½ gr. (B)

These pills are admirably adapted for the assimilation of iron, as the ingredients re act upon each other to form Ferrous Carbonate which, owing to the protection afforded by the soluble coating, remains unaltered until freed for action by the stomach juices.

No. 468 **FERRUGINOUS (Blaud's) COMP. IMP.**

Ferri Sulphatis,	2½ gr.
Potassii Carbonatis,	2½ gr.
Acidi Arsenosi,	1-50 gr.
Ext. Nucis Vomicæ,	1-8 gr.
Ext. Cascaræ Sagradæ,	1 gr.

No. 262 **IPECAC. ET OPII** (Dover's Powder), 2 gr.

No. 263 **IPECAC. ET OPII** (Dover's Powder), 5 gr.

No. 303 **OPII ET CAMPHORÆ**

Pulv. Opii,	1 gr.
Camphoræ,	2 gr.

No. 304 **OPII, CAMPHORÆ ET ACIDI TANNICI**

Pulv. Opii,	¼ gr.
Camphoræ,	1 gr.
Acidi Tannici,	2 gr.

No. 390 **QUININÆ, FERRI, ET STRYCHNINÆ VALERIANAT**

Quininæ Valerianat.,	1 gr.
Ferri Valerianat.,	1 gr.
Strychninæ Valerianat.,	1-60 gr.

No. 391 **QUININÆ, FERRI, ET ZINCI VALERIANAT.**

Quininæ Valerianat.,	1 gr.
Ferri Valerianat.,	1 gr.
Zinci Valerianat.,	1 gr.

No. 405 **RHINITIS (Dr. Rhodes)**

Ext. Belladonnæ Fol.,	1-12 gr.
Camphoræ,	1 gr.
Quininæ Hydrochlor.,	1½ gr.

Dr. J. Edwin Rhodes says: "The Pil. Rhinitis may be used with benefit in those cases commonly called 'a cold in the head.' If one pill is taken every three or four hours during the acute stage after free secretion from the mucous membrane has set in, they will often abort a cold in a few hours, and cut short an attack that might otherwise continue for a number of days."

No. 438 **TERPINI HYDRATIS**, 2 gr.

No. 439 **TERPINI HYDRATIS**, 5 gr.

In prescribing, please specify "**SCHIEFFELIN.**"

Harveian Lectures

ON

SYPHILITIC DISEASES OF THE EYE AND ITS APPENDAGES.

Delivered before the Harveian Society

BY HENRY E. JULER, F.R.C.S. ENG.,

OPHTHALMIC SURGEON TO ST. MARY'S HOSPITAL; SURGEON TO THE ROYAL WESTMINSTER OPHTHALMIC HOSPITAL; AND CONSULTING OPHTHALMIC SURGEON TO THE LONDON LOCK HOSPITALS.

LECTURE I.[1]

Delivered on Dec. 2nd, 1897.

SYPHILITIC DISEASES OF THE EYELIDS.

MR. PRESIDENT AND GENTLEMEN,—Chancres of the eyelid are always hard or infecting sores. Soft or locally contagious sores are never seen in this region. There is not according to Panas[2] a single authenticated case of a soft chancre attacking the eyelid recorded. To quote the great English authority on syphilis: "It is a remarkable fact that the non-indurated sore is almost never seen except on the genitals" (Jonathan Hutchinson). Chancres of the eyelids involve with very few exceptions the palpebral conjunctiva. Rarely they may be seen limited to the cutaneous surface of the eyelid on the one hand or the conjunctival surface on the other. The frequency of primary syphilitic lesions here compared with those elsewhere is difficult to determine with any degree of accuracy and, based on de Beck's[3] valuable researches, varies within wide limits in different countries. He considers that in France it is reasonable to expect a palpebral chancre once in every five hundred cases of syphilis. This, in my opinion, far exceeds its relative frequency in this country. In Germany, also, this would be considered excessive. Though the situation of a chancre is in most instances on the lid margins spreading on to the palpebral conjunctiva they may start on the caruncle or plica semilunaris and involve the two eyelids at their junction, the inner canthus. Infants and young children run a risk of inoculation by the kisses of infected persons. It is a pernicious habit and mothers should not allow their offspring to be kissed by anyone indiscriminately. On the other hand nurses may be infected by a syphilitic infant. The following is a case in point:—

CASE 1.—A woman, aged forty-five years, came under my care at St. Mary's Hospital suffering from an irregular ulcer at the inner canthus which had resisted treatment for three weeks. The pre-auricular gland and one submaxillary lymphatic gland were enlarged. She had been nursing a baby with evidences of congenital syphilis—viz., ulcers around the mouth, snuffles, and sores on the soles of the feet when three months old. The ulcer was not much indurated nor were the eyelids much swollen. It was surrounded by a red zone, had a grey surface, and very little discharge. The ocular conjunctiva was injected to the inner side. The nature of the lesion was suspected. My colleagues, Mr. Anderson Critchett and Mr. Ernest Lane, confirmed my opinion and advised the suspension of antisyphilitic remedies till the secondary symptoms appeared. A month later she developed a roseolous rash, a sore throat, and syphilitic onychia. Subsequently the rash became a tuberculous syphilide. The ulcer healed readily under the influence of mercury, but epiphora resulted from the involvement of the canaliculi in the scar

Kissing the eyelids is recorded as an instance of contagion. The introduction of the virus by the finger is perhaps the most common mode of inoculation. Medical men and midwives especially have been known to fall victims in this way. As the finger is so often placed on the caruncle to remove mucus or relieve irritation it is not surprising that we find chancres at the inner canthus.

The clinical course of these erratic chancres differs immaterially from those elsewhere. It is necessary, by the way, to remember that the amount of local reaction varies greatly. I have seen the eyelids considerably swollen with chemosis of the ocular conjunctiva, but inflammatory troubles of this nature are the exception. It is not uncommon to find a chancre extending throughout the length of the eyelid either by the coalescence of two or more primary lesions, such as may be acquired by treating blepharitis in the manner described above, or by a single chancre spreading along the lid-margin. Phagedæna, however, of the eyelid is practically unknown. The outline of the sore is usually circular or oval but may be very irregular. Similarly, there may be an absence of the usual induration.

Certain complications may occur locally which are of interest. The canaliculi may be strangulated in the contraction of the cicatrix, which happened in the case described, and epiphora ensued as a consequence. Again, a chancre may spread from the palpebral conjunctiva on to the ocular and in the healing process symblepharon may result. The pre-auricular gland is always enlarged, firm, and painless, and not tender unless manipulated roughly. I know of no instance in which in an undoubted case the former was not perceptibly swollen and hard. The absence of tenderness has a diagnostic significance. The diagnosis of primary syphilitic sores in this region constitutes one of the most interesting problems in surgery. It may be mistaken for any one of the following lesions: rodent ulcer, epithelioma, lupus, chalazion, hordeolum, and tuberculous ulcer of the palpebral conjunctiva.

Chancre of the eyelid is always accompanied by enlargement and induration of the pre-auricular or submaxillary gland, usually both; the absence, therefore, of glandular swelling will help to exclude many of the above affections. Thus rodent ulcer, tertiary syphilitic ulcer, lupus, and in most instances chalazion and hordeolum may be excluded, for in all of these the pre-auricular gland seldom, if ever, becomes enlarged. I have known both eyelids removed for suspected rodent ulcer; the growth proved to be epithelioma and yet the pre-auricular gland could not be felt. By the time that an epitheliomatous ulcer caused enlargement of the gland a chancre would have healed spontaneously and the sufferer be half through the secondary stage of syphilis. With suppurating chalazion and large suppurating styes the pre-auricular gland may be infected, but in such cases it is much swollen, painful, very tender, and the skin over it is red and œdematous. It is an acute lymphadenitis easily distinguished from a chronic enlargement. By a process of exclusion only one ulcer is left, the tuberculous ulcer of the conjunctiva, which is sufficiently rare to have been very much overlooked in literature. In my opinion this is the only ulcer that is likely to be mistaken for a chancre. The pre-auricular gland is firm and swollen and the ulcer is either round or oval and saucer-shaped. Be suspicious if there is no induration at the base of the ulcer. A tuberculous ulcer I have learned from experience is never indurated. The following are two cases of tuberculous ulcers of the palpebral conjunctiva which came under my care and which were at first mistaken for chancre.

CASE 2.—A girl, aged thirteen years, came to the ophthalmic department at St. Mary's Hospital complaining of a discharge from her right eye attended with slight pain and discomfort. On examination a purulent discharge was seen in the conjunctival sac and slight redness of the eyeball. On everting the upper eyelid an ulcer on its inner surface was seen as large as a split pea, saucer-shaped but without induration. The pre-auricular gland was enlarged and tender. It was thought that the ulcer might be a chancre and the child was treated with grey powder. At the end of five weeks it was no better and as she was looking so ill and complained of headache she was admitted as an in-patient. Her temperature was 100·4° F. and her general condition rapidly became worse. Losing consciousness a week later she developed an internal strabismus and slight optic neuritis and died a few days later. The necropsy revealed tuberculous meningitis.

The second case is also a good illustration of a tuberculous conjunctival ulcer which likewise proved fatal in an almost similar way to the last.

CASE 3.—A girl, aged six years, was brought to me for redness of the right upper eyelid. Upon everting it an oval ulcer was exposed 12 mm. long and about 6 mm. wide situated near the outer canthus and depressed in its centre with margins slightly raised and granular. The surface of the ulcer was smooth, clean, and pale pink in colour. There

[1] Lecture II. was delivered on Dec. 9th and Lecture III. will be delivered on Dec. 16th, 1897.

[2] Traité des Maladies des Yeux, 1894, vol. ii.

[3] Hard Chancre of the Eyelids and Conjunctiva, Cincinnati, 1886.

Digitized by Google

was no induration of its base. The cutaneous surface of the eyelid in its vicinity was slightly swollen and red and the ulcer secreted a muco-purulent discharge. The pre-auricular gland was swollen as large as a haricot bean and was tender. The glandulæ concatenatæ could be felt but were not much enlarged as also the submaxillary lymphatic glands. A month later a similar ulcer developed on the lower eyelid. There was a small lupus-looking nodule on the right cheek but beyond this no cutaneous trouble. On the whole she was a healthy-looking child with a bright, florid complexion. The only family history of any importance was the death of the girl's grandmother on her mother's side from phthisis. Two months later the patient died from general tuberculosis.

I do not apologise for describing both these cases of tuberculous ulcers of the conjunctiva for they are rare and in each instance the diagnosis of chancre was made. As the prognosis differs widely in each it is well to have some distinguishing features of importance. The absence of induration, the smooth, clean, pale pink surface of the ulcer, and the tenderness of the enlarged pre-auricular gland are the chief points in these cases worthy of notice.

The treatment of chancre of the eyelid should not be undertaken till the diagnosis is confirmed by the development of secondary manifestations of syphilis. It is possible, if not probable, that mercury in the first case aggravated the local and probably primary tuberculous lesion and increased the predisposition to general infection, so in a two-fold manner hastening the end. When it is proved beyond doubt to be a syphilitic sore measures for its cure, local and constitutional, should be at once adopted. Locally, dusting calomel or iodoform powder on the ulcer is advisable as well as bathing the sore with black wash or weak perchloride of mercury lotion.

TERTIARY MANIFESTATIONS.

Gummata occasionally appear in the skin and subcutaneous tissue superficial to the tarsus or may develop in the substance of the latter. The cutaneous lesions soon ulcerate and a punched-out ulcer occupies the place. In the tarsus they do not break down so early and are easily mistaken for chronically inflamed Meibomian cysts. Trousseau[4] has paid much attention to gummata of the palpebral conjunctiva and describes two clinical varieties, the chronic and the acute. The latter resembles an acutely inflamed chalazion attended with œdema of the eyelids, the skin dusky red or of a purplish hue, enlargement of the pre-auricular and submaxillary glands, and with marked muco-purulent discharge. I do not think that we are in a position to attribute this acute inflammatory lesion to syphilis. It is possible that a gummatous deposit in the eyelid might become infected by pyogenic organisms and so be the cause of the distinction made by Trousseau, but a suppurative process acute from the onset in a syphilitic subject must be *post hoc* not *propter hoc*. Syphilitic tarsitis or diffuse inflammatory infiltration of the tarsus caused by syphilis is a rare affection and so far I can only remember seeing two cases which at all agreed with the description given by Stedman Bull.[5] I will describe the affection in his own words: "It is a chronic indolent infiltration of the tarsus which does not involve the skin. This process is not, however, always indolent or passive. It is usually accompanied by little œdema of the conjunctiva and swelling of the rest of the eyelid. It is almost always in the upper lid and generally involves its whole from inner to outer canthus, though it may be circumscribed. After the disappearance the tarsus is found to have entirely lost its normal resistance. There is no pain and no secretion from the conjunctiva and the disease is of slow progress. The tumour is hard, resisting and solid. The lid cannot be everted. The swelling is homogeneous throughout and though starting in the tarsus usually involves the other tissues of the lid with the exception of the skin and perhaps the conjunctiva also. After the dense infiltration has somewhat subsided under appropriate treatment so that the lid may be everted there may be seen in various places under the conjunctiva a brawny, yellowish-white infiltration of the tissues which slowly subsides. The cure is probably never a complete one, for after the absorption of so extensive and dense an infiltration more or less deformity of the tarsus must and does result from compression or softening of the tarsal tissue." We are led to believe from Bull's description that the inflammation starts primarily in the fibrous tissue, but according to Panas such is rarely the case. He believes the glands of Meibomius are first involved and lays but little stress upon its syphilitic origin. Michel and others have reported cases of syphilitic tarsitis. A recent case under my care presented all the appearances of the above affection but is not an uncomplicated case.

CASE 4.—A man, aged thirty-four years, married, had syphilis about fifteen years ago with rupial sores. He had had weak eyes from childhood. The right eye presented a leucoma adherens from a perforating ulcer six years ago. The left upper eyelid presented a swollen appearance with redness of the skin. It was firm and much thickened throughout its greater part and resembled numerous cysts blended together. There was no thinning of the ocular conjunctiva corresponding to the supposed cysts. The swelling had existed for fourteen days, but he had been attending for some months for treatment for trachoma. Iodide of potassium was prescribed and he is now well.

CASE 5.—A similar case is that of a married woman who was under my care about six years ago with a similar diffuse swelling of the tarsus in the upper and lower eyelid on one side. Like the case above she had a coarse acneform eruption on her face but no trachoma or any history of syphilis. Though numerous incisions were made into the nodular masses nothing could be scraped out. It subsided eventually under iodide of potassium.

Whether these cases of thickened tarsi, homogeneous on section, diffuse in nature, and yielding only to iodide of potassium, are syphilitic manifestations has yet to be proved.

THE LACRYMAL APPARATUS.

Syphilitic dacryo-adenitis either in the form of a diffuse interstitial adenitis or of gummata is not known—i.e., there is no undoubted case yet placed on record. Syphilitic lesions are equally unknown in the salivary glands, they are rare in the pancreas. Instances have been published by Alexander, Bull, and others in which the lacrymal gland has participated in the infective process, but in none could it be ascertained that the periosteum was not the primary seat of the lesion. Bull says that he has seen a case in which the gland upon examination was found hypertrophied from connective tissue growth and gummatous infiltration. The patient died from a gumma of the dura mater.

Symmetrical enlargement of the lacrymal glands is, perhaps, one of the rarer affections of the appendages we are liable to meet with and I have but little hesitation in attributing many instances of this condition to syphilis. Further researches have yet to be made in the pathological histology of these cases before we can assert that the gland is the original seat of the mischief. If it eventually proves to be so it is very certain that the inflammation spreads far beyond the confines of that organ. It has been my lot to come across two, if not more, cases of this kind, which, in spite of imperfect histories of venereal trouble, I have believed to be syphilitic and they have yielded in a satisfactory manner to antisyphilitic treatment. The last case is reported in the Transactions of the Ophthalmological Society (vol. xii., p. 44), and at that time was shown at its acme as a case of symmetrical tumours of both orbits probably sarcomatous. Since then they have under iodide of potassium and mercury completely disappeared. I will give the details of the case as briefly as possible.

CASE 6.—A woman, aged forty-five years, came under my care in May, 1891, with slight redness, mistiness, and lacrymation of the left eye. Vision was normal in each eye. She was ordered glasses and treated for slight conjunctivitis. Two months later she consulted me again for a nodule that had appeared a month ago above and to the outer side of the left eye, stating that it had increased in size and that one had appeared in the same position over the right eye. I found what appeared to be enlargement of the left lacrymal gland, but could detect no nodule in the right orbit. The eyes were both congested. She was a very stout, plethoric woman and suffered from glycosuria. She had lived twenty-two years in Paris and she gave a history of four successive stillbirths. She was treated with iodide of potassium and codeia. This tumour slowly increased in size, but on Aug. 17th a distinct swelling was found in the right orbit, œdema was present in both upper lids, there was chemosis of the conjunctiva, and ptosis was present on the right side. Movements of the eyeballs were fairly good. Subsequently, in spite of treatment, the growths increased and almost complete anæsthesia

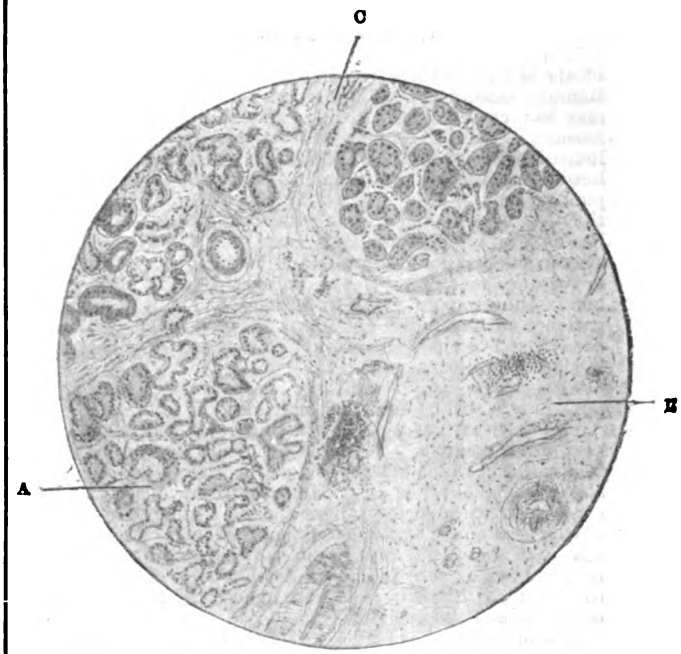
[4] Société Française d'Ophtamologie, 1888.
[5] Morrow's System of Genito-urinary Diseases, vol. ii., part ii., p. 547.

Digitized by Google

of the left half of her forehead became manifest, also limitations of the movements of both eyes in every direction. The tumours were hard and nodular, and arched over both eyeballs to near the inner canthi (Fig. 1). With a view to clearing up the diagnosis I elected

FIG. 1.

Symmetrical enlargement of the lacrymal glands.



to cut down upon the tumour of the right orbit for microscopic investigation. Sections of a piece removed showed the growth to consist of spindle and round cells. Iodide of potassium was persistently continued with increasing doses. Mercury was now added to this. Having reached their acme in December the tumours began slowly to subside. A year later the eyes and orbits had regained their normal state. No swelling, only slight ptosis, no anæsthesia, no limitation in movement, or any evidence of former trouble existed in the early part of 1895. Mr. Adams Frost, Mr. Hutchinson, and Mr. Nettleship saw the case in consultation at different times and two were of opinion that the growths were syphilitic. At the Ophthalmological Society the general opinion was that it was either syphilitic or sarcomatous. I had scarcely a doubt in my mind that this was an instance of enlargement of the lacrymal glands due to either a chronic interstitial adenitis or a peri-adenitis due to syphilis. Especially as in addition to the history of four successive stillbirths I found distinct scars of deep ulceration above the left groin. She was seen again in 1894 by Dr. Tom Robinson who informs me that there was still slight ptosis but that the eyes were otherwise fairly well. She had, however, "an enormous distribution of cutaneous gummata interspersed here and there with cicatrices which were more or less sickle-shaped. They disappeared under a course of mercuric perchloride with inunctions of iodide of lead ointment. In 1896 she developed rapid phthisis, wasted very much, and died in October."

A similar case to this has been recorded by Adams Frost.[6] Symmetrical tumours of the orbit appearing at the upper and outer part have been proved clinically and by microscopic examination to be lympho-sarcomata, the diagnosis therefore is rendered especially difficult by the tendency which these syphilomata have to persist, and steadily increase in spite of treatment, and we find that it is only after a very prolonged course of iodide of potassium with increasing doses that they yield. To make a diagnosis it is well to make an early exploratory incision and remove a piece of the growth of sufficient magnitude to be certain of its nature by microscopy. Bearing in mind the rarity of dacryo-adenitis it is merely a hypothesis that the glands are primarily the seat of the inflammation, but instances have been recorded in which the swelling has been examined and found to be the lacrymal gland enlarged and, by the microscope, interstitially inflamed.

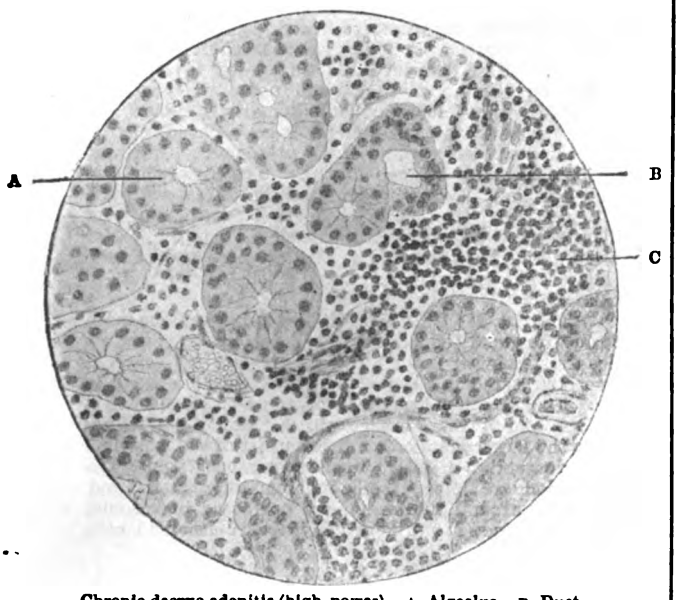
CASE 7.—The patient, a girl aged five years, was under Mr. Wainwright's care in November, 1892. A tumour about the size of a Brazil nut was situated in the region of the lacrymal gland. It appeared as if the latter was greatly enlarged. The eye itself appeared normal and the vision was good. The temperature and pulse were normal. The history given (unreliable) was that the swelling had come on suddenly a month previously and had not increased or diminished since. The swelling was punctured in several places with a hypodermic syringe but nothing but bloody serum was withdrawn. As the swelling increased in size the contents of the orbit were removed on the suspicion that the growth was sarcomatous. The tumour was found to involve the periosteum on the upper, inner, and outer walls of the orbit, completely enveloping the lacrymal gland, and extended as far back as the optic foramen. The discharge from the orbit was profuse and purulent for some time, but eventually the cavity became closed. The history of the case and especially the antecedents of the parents were, I regret to say, not recorded in the notes; the diagnosis of syphilis is based entirely upon the pathologist's report. Nor can I learn whether the child is still alive as the parents have left their former residence and their whereabouts is also unknown.

The pathologist, Mr. John Griffith, has furnished me with sections of the gland (which are here under the microscope) and also the following report: "Contents of orbit removed for suspected sarcoma Dec. 22nd, 1892. The eyeball is healthy. The growth is firm and lobulated and consists of a large piece and a few smaller pieces. Examined microscopically the larger mass is found to consist of the lacrymal gland and dense fibro-cellular, peri-adenomatous tissue. The smaller portions are simply chronic inflammatory material and like the tissue around the gland, are composed of vascular fibro-cellular tissue (Fig. 2). Formative or epithelioid cells

FIG. 2.

Lacrymal gland (low power). A, A lobule. B, Thickened capsule. C, Thickened trabeculæ.

are grouped more especially around the smaller blood-vessels, but they are to be recognised in all parts organising fibrous tissue. The blood-vessels are healthy. The capsule of the gland is considerably thickened as also the trabeculæ; the peripheral lobules are consequently much separated. Within the lobules the sustentacular tissue is more cellular than in health. The condition is one of chronic periostitis and peri-dacryo-adenitis. I believe it to be a syphilitic change, analogous to syphilitic peri-hepatitis." If, as there is reason to believe, this was caused by syphilis it was probably the hereditary form and should



[6] Transactions of the Ophthalmological Society, vol. vii., p. 112.

Digitized by Google

come within the category of the third lecture, but I have thought it advisable to bring it before your notice now as it tends to throw some light upon the nature of these symmetrical tumours of the orbit starting in the vicinity of the lacrymal glands.

To recapitulate, these tumours start in the upper and outer part of the orbit, first in one then in the other. Small nodules are felt at first which multiply until symmetrical lobulated tumours exist arching inwards over the eyeball.

FIG. 3.

Chronic dacryo-adenitis (high power). A, Alveolus. B, Duct. C, Inflammatory cells.

Ptosis is the first obvious sign though puffiness and even slight redness of the eyelids may be noticed. The periosteum may be very extensively involved so that nerves and even the muscles at their origin may be interfered with, giving rise to limited movement of the eyeball and anæsthesia of the forehead and scalp. There is no papillitis, the eyeballs do not pulsate nor are they invaded by the growth. The close of the disease leaves the eyes as perfect as before. From what has been said, therefore, it is clear that the treatment consists in the persistent exhibition of iodide of potassium with or without mercury. Weeks or even months may elapse before the tumours yield to treatment. It is a game of patience on both sides and must be persevered with. The dose should be slowly increased and only temporarily reduced if signs of iodism appear.

Though the conjunctival sac is part of the lacrymal apparatus it will be dealt with separately.

The lacrymal caruncle at the inner canthus may be the seat of a chancre. It may participate in the catarrhal inflammation which attacks the conjunctiva in the secondary stage of syphilis. It is possible for a mucous patch or a condyloma to be present here though I do not remember having seen one. A gummatous infiltration of the caruncle has been described by Taylor, of New York, who has reported two cases. In each a firm globular enlargement of the caruncle existed, deep red in colour, and protruded outside the closed eyelids.

Syphilitic affections of the lacrymal passages are not at all uncommon, and though the nasal duct is implicated more in hereditary syphilis, the acquired disease is a very frequent cause of lacrymal obstruction, and usually the severer forms in which necrosis or caries is present. The puncta and canaliculi may be obliterated by cicatrisation of a chancre or of a tertiary ulceration. A gumma of the caruncle may give rise by pressure on the canaliculi to epiphora, and the lacrymal sac may be opened up by an ulcer with a fistula as a result. During secondary syphilis secretion may be pent up in the sac from inflammatory swelling of the muco periosteum of the nasal duct, or by mucous patches at its opening in the inferior meatus. In each case there is a tendency for a catarrhal dacryo-cystitis to become purulent. A lacrymal abscess, however, is more liable to occur in the later stage of syphilis. Obstruction in the nasal duct is essential to the formation of a lacrymal abscess. A mucocele or chronic dacryo-adenitis is brought about in the same way. Any acute or chronic swelling of the muco-periosteum is a factor in the causation of one or the other.

Tertiary syphilis obliterates the lumen of the canal by causing a muco-periostitis more or less chronic. In some cases the syphilitic deposit in this lining membrane breaks down and necrosis occurs or the change is less active and caries or caries-necrotica is the result. At the junction of the sac with the duct, the narrowest part of the passage, the stenosis is complete and shuts off the sac above from the nasal duct below. If the sufferer is seen in an early stage the stricture may be dilated without gross changes taking place in the duct, but if neglected certain forms of gummatous muco-periostitis undergo secondary changes with destruction of the bony wall, and upon passing the stricture the probe passes into a large cavity of broken down gummatous material and the bony wall if not much destroyed can be felt rough as the probe grates against it.

The treatment resolves itself into keeping the canal patent, washing it through daily or three times a week with a solution of perchloride of mercury and giving internal anti-syphilitic remedies. These cases often have ozæna with extensive disease in the nose which must have simultaneous attention.

CONJUNCTIVA.

In dealing with primary and tertiary ulcerations of the eyelid the palpebral conjunctiva was included. Besides chancres on the palpebral the primary sore has been seen on the ocular conjunctiva, also in the folds of the fornix. In the process of cicatrisation the latter will, to a varying extent, cause adhesions of the palpebral and ocular surfaces of the membrane. Much deformity, however, is rare. A form of catarrhal conjunctivitis often occurs as a secondary manifestation preceding an attack of iritis. The ocular conjunctiva is much congested and there is a muco-purulent discharge. It is owing to this catarrh that syphilitic iritis is sometimes neglected, for the one runs imperceptibly into the other; on the other hand, the redness of the eyeball may lead to the early use of atropine and prevent an impending attack of iritis. The catarrh is usually symmetrical. Other secondary affections of the conjunctiva as condylomata, mucous patches, &c. I have never had the opportunity of witnessing.

THE ORBIT.

The most prominent part of the orbital rim is the upper and outer angle, that formed by the external angular process of the frontal bone. Syphilis predisposes to periostitis, and as a tertiary phenomenon a gumma of the periosteum is a common lesion. It is seldom, however, that a gumma develops without an exciting cause and usually a blow, slight in character and possibly unnoticed, is the determining agent. We are not surprised, therefore, if a gumma develops in the periosteum at the upper and outer part of the orbit. The following is an illustration.

CASE 8.—A woman, aged fifty-six years, in November, 1890, attended my clinique with a swelling over the external angular process of the frontal bone on the right side extending beneath the orbital rim. It had been noticed for three weeks and was growing larger. The swelling had a smooth uniform surface, elastic, almost fluctuating, and of about the size of a small walnut. The skin was normal over it and moveable. It was doubtful whether the lacrymal gland was involved or not. The eye appeared to be pushed downwards though there was no diplopia, nor were the movements of the eyeball limited (Fig. 4). She had had no children or miscarriages. There was extensive scarring about the left knee which she admitted were due to "holes about the knee which came by themselves." They were distinctly scars of old syphilitic ulcers. Under iodide of potassium the orbital tumour rapidly disappeared so that in the following January there was no trace of the swelling left.

I could quote several similar cases, for they are not rare, and unlike the former orbital growths of which I have spoken they are quickly cured by iodides. The diagnosis is in many instances rendered easy by the existence of gummata elsewhere. It is a curious fact that in one year I saw two cases of gumma of the clavicle associated with gumma of the orbit. The chief features to be noticed in these cases are the following. Displacement of the eyeball; this varies with the site of the tumour. In most instances there is slight

Digitized by Google

proptosis. If the growth is above as is more often the case there will be ptosis, chiefly mechanical. Double vision though not invariably present is a common symptom. Signs of inflammation are usually conspicuous by their absence.

Retro-ocular neuritis has lately received much attention abroad as well as in this country. Only last March this subject was ably introduced by Mr. Marcus Gunn and Dr. Buzzard[7] at the Ophthalmological Society, and a keen discussion ensued. The chief clinical features of such cases are, according to Mr. Gunn, "rapid failure of vision, usually in one eye only, often accompanied by pain and tenderness in the neighbourhood, absence of early ophthalmoscopic changes, and a tendency to recovery." To these let me add a central absolute scotoma as a frequent though not constant symptom. The absence of early changes in the fundus oculi does not exclude the possibility of gross lesions, for I have myself had the opportunity of seeing pronounced

FIG. 4.

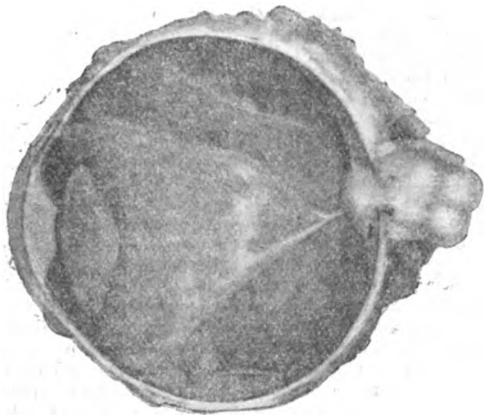
Syphilitic periostitis of orbit.

papillitis in cases of retro-bulbar interstitial optic neuritis caused by syphilis. It is, moreover, usual to find pallor of the optic discs without a preceding papillitis. Syphilis is only one of the various diseases which is attributed as a cause of this complaint.

If the trouble is limited to one eye we have every reason to suppose that the lesion is intra-orbital, and, in the absence of papillitis, situated far back. Hence we may surmise that a local periostitis in or near the optic foramen is, in some instances, the lesion. We cannot, however, explain the cause of the central scotoma in a satisfactory manner. Mr. Nettleship[8] says: "It is not so easy to draw a good distinction, save ophthalmoscopically, between the cases now specially referred to"—namely, cases of retro-ocular neuritis in one eye, with loss of vision, neuralgic pain about the orbit and temple, and little or no ophthalmoscopic change, "and those much more rarely seen in which single violent papillitis occurs with severe localised pain and sometimes paralysis of other nerves in the same orbit." I have seen at least half a dozen of these rarer cases and feel convinced in my own mind that they are the result of an interstitial optic neuritis immediately behind the eyeball. Moreover, I can bring forward a proof that this if not invariably is sometimes the case. Allow me first of all to quote an instance which I published in the Transactions of the Ophthalmological Society[9] with my views which at that time were wanting in facts in spite of the strong evidence of the clinical details. Subsequently I proved microscopically the truth of my assertion in examining the optic nerve of an eye of a parallel case.

CASE 9.—A woman, aged twenty-eight years, attended the Royal Westminster Ophthalmic Hospital on Feb. 3rd, 1894, complaining of loss of sight in her right eye and intense pain in her head. "Her sight was perfectly good till the latter end of November, 1893, when she first noticed that her sight was failing in her right eye, and in three weeks from that date it was quite blind." She was a married woman, though separated from her husband, had three children, the youngest having been born in September, 1893. She together with her youngest child had been treated for syphilis. There was no doubt about syphilis. There was no other recent illness. The right eye was quite blind; the pupil only responded consensually to light. There was very pronounced papillitis with much swelling. There was slight divergence of the right eye, but the conjugate movements were good. There was no local or general paralysis, no proptosis, and no swelling of eyelids. The left eye was normal in every respect. Beyond the severe hemicranial headache and the loss of vision there was no other symptom. There was no history of vomiting, vertigo, or fits.

The following remarks I made at the time I showed the patient at the society. "This case resembles one of those rarer forms of retro-ocular neuritis attended with profound papillitis and intense headache mentioned in a paper by Mr. Nettleship at this society [Ophthalmological] in 1884. The early, rapid, and complete loss of sight on one side only combined with loss of direct light reflex points to the lesion being intra-orbital rather than intra-cranial and involving early and completely the optic nerve. The absence of any other sign of orbital tumour, as proptosis, limited movement, vascular disturbances, and the like, suggests the lesion being within rather than outside the nerve. I am inclined to look upon it as a diffuse interstitial neuritis due to syphilis. The pain disappeared and the papillitis subsided under anti-syphilitic treatment, and perception of light returned for a time, though finally the eye became quite blind." Since then, four years ago, I have not only had no reason to change my views but have had an opportunity of strengthening them by the examination of an eye together with the optic nerve of a similar case, which was shown and described by me at the French Ophthalmological Society[10] last May.



CASE 10.—A man, aged fifty-two years, contracted syphilis in April, 1894. He was treated at that time with iodide of potassium and mercury and all symptoms disappeared. In July, 1896, he noticed that the sight of the left eye was beginning to fail. He lost first of all the inner half of his left visual field, then the outer half, until his sight went altogether. After the loss of his sight, on July 26th, the eye became inflamed and very painful. His sufferings were increased on the slightest movement of the eye. He was at that time on the sea, where he was leeched, the eye was fomented and atropised, but without relief. When I saw him for the first time in August, 1896, he was absolutely blind with the left eye. The tension was normal; there was slight iritis with complete posterior synechia. It was impossible to see the fundus oculi. There was severe pain round the orbit. All the remedies—fomentations, leeches, atropine, opium—were given without relief. An intra-ocular tumour was suspected, so the eye was excised on Aug. 26th, 1896. The operation was followed by a complete relief from pain. The right eye was normal and its vision was good. There was nothing indicative of intracranial trouble. In the middle of September the patient experienced intense pain in the popliteal region; the pain extended to the foot and he was unable to walk. In October he had severe and prolonged inflammation of the throat. In November there appeared large bright-red thickened patches on the skin of the forehead, the cheeks, the shoulders, and the back; these increased to such an extent that the forehead and the face were completely covered; several of these commenced to ulcerate at the centre and to suppurate. The patient was seen by Mr. Malcolm Morris, who was of opinion that the disease was due to syphilis, but that the case appeared like, and might possibly be, one of leprosy. Careful search was made in the discharges for the leprosy bacillus, but with a negative result. The patient suffered greatly from diarrhœa and became so feeble that I was afraid he would not live. He was kept in bed, carefully nourished, and treated with mercurial inunctions. The diarrhœa ceased and the pains in the leg disappeared. The skin rapidly healed

and the patient regained perfect health in the course of two months. I heard from him only the other day and he reported that he had continued well ever since his return to one of the colonies. The extirpated eye was hardened in formol and on section exhibited several points of interest. The papilla was greatly swollen (see Fig. 5) and the adjacent

FIG. 5.

Interstitial retrobulbar optic neuritis and papillitis.

retina was much thickened; the latter was detached on the left side and was of a mahogany colour. The optic nerve was nearly twice its normal thickness, being 6 mm. in diameter immediately behind the globe of the eye. It presented longitudinal striations alternately white and grey. There was a diffuse cloudy opacity of the vitreous humour with interruptions of membranous bands of which one passed forwards and inwards from the summit of the swollen papilla. The pupil was blocked with lymph. The lens was normal. Under the microscope the optic papilla was found to be infiltrated with leucocytes; the nerve-fibre layer of the retina also showed this dense cellular infiltration, whilst the outer layer of the retina had undergone the plication or folding which is ordinarily found in cases of severe papillitis. The nerve itself near the globe of the eye was entirely blocked with leucocytes whilst further back these cells were grouped in compressed masses around the blood-vessels. The choroid also presented diffuse cellular infiltration. The mahogany patches of the retina proved to be extravasations of blood chiefly occupying the nerve-fibre layer.

This case is full of interest not merely to ophthalmologists but to all clinical observers and pathologists. In the first place it is undoubtedly a case of inflammation of the optic nerve behind the eyeball near to and invading the papilla. This is proved by the swelling and infiltration of leucocytes. It is not a simple œdema of the papilla and its surroundings as one frequently finds in cases of papillitis due to intracranial tumours. Secondly, there is no question about the case being one of acquired syphilis. The other lesions which followed the excision of the eye, the cutaneous eruption and the peripheral neuritis of the leg, proved that it was a case of delayed secondary syphilis. In this particular instance the inflammatory exudation is very pronounced within as well as behind the globe; but one can easily imagine a similar inflammation of less severity in the same region and due to the same cause.

The cause of retrobulbar neuritis where the presence of a central scotoma is the chief symptom and where the ophthalmoscope reveals no change beyond perhaps slight pallor of the disc is often very obscure. In observing the cases which have come under my care, all being treated and many cured by mercury (excluding tobacco amblyopia), I am persuaded that the principal cause was a syphilitic inflammation of the optic nerve. The most marked case was that of a man who had recently contracted syphilis; he had papillitis and a large central scotoma for colours in each eye. His vision was less than Jaeger 20, but he was completely cured, recovering vision in both eyes after prolonged treatment by mercurial inunctions.

Besides the optic nerve, other nerves in the orbit, the motor nerves especially, may have their function impaired with varied palsies of the extra- and intra-ocular muscles, from syphilitic affections. We have no evidence at present pointing to the lesions being peripheral or orbital. So far as we understand their pathology we know that the majority of the cases of ocular paralysis are due to syphilis acting upon the motor nerves of the eye before they pass out of the cranial cavity through the sphenoidal fissure. When we consider the manifold ways in which syphilis may act directly upon these nerves it is not surprising. The anatomical seat is as varied as the nature of the syphilitic lesion. From the nuclei of the third, fourth, and sixth nerves to their entry into the orbit there is a possibility for syphilis to interfere with them by gummata, pachymeningitis, aneurysms, hæmorrhages, thrombosis, &c. I will not, however, weary you by giving instances of such every-day complaints nor is it my intention to wander from the domains of ophthalmic surgery into the more intricate and subtle provinces of the neurologist.

ABSTRACT OF A

Presidential Address

ON

THE INTERNATIONAL SANITARY CONFERENCES OF THE VICTORIAN ERA.

Delivered before the Epidemiological Society of London on Nov. 19th, 1897.

BY J. LANE NOTTER, M.D. DUB.,

PROFESSOR OF MILITARY HYGIENE, ARMY MEDICAL SCHOOL, NETLEY.

GENTLEMEN,—It seems to me that a review of the growth and position of the knowledge of the infective diseases as guiding the methods of prevention taken by the various European States, especially as regards the possible introduction of epidemic disease from the east into Europe, may offer a theme for a presidential address not in itself uninteresting or unprofitable. Such a view will emphasise the fact that England through all these conferences has gradually educated Europe to the true principles of self-defence which have been the means of relieving many a State of the old system of quarantine, a system based upon false principles, adverse to all sanitary improvements, ruinous to trade and to commercial development, and utterly out of date with modern scientific knowledge.

The first suggestion of an international conference was made by the French Government in 1838, but so diverse were the views held on the subject of quarantine and its enforcement at stations and ports on the Mediterranean that the proposals fell through owing to various difficulties which arose. Again in 1843 the British Government suggested a further conference; but this again was opposed by Austria as premature as there was no information on which to found regulations which would be acceptable to the Powers. The wave of cholera epidemics which passed over Europe, and especially over Ireland and other parts of the United Kingdom, in 1849–50 brought the subject again prominently under notice and accordingly we find the French Government again taking the initiative and a conference assembled in Paris in 1851 to consider the question of quarantine in relation to cholera, yellow fever, and plague, the only diseases in which this means of prevention was to be employed. For all practical purposes the results of this conference were unsatisfactory; there was little unity of opinion and no system of international control was possible under the circumstances. It was not until 1865 that the consideration of the question of international control began to be seriously considered. The developments of trade and commerce with the introduction of steam transport and the inconvenience to which the ship-owners were subject demanded that some official pronouncement should be made. It rested with the medical officer to the Privy Council to raise the question and it was chiefly owing to the masterly exposition of his views expressed by Sir John Simon in the report of the Local Government Board for that year that the subject assumed the position of scientific inquiry which has ultimately led step by step to the almost total abolition of quarantine not only in England but in countries under international control.

Digitized by Google

That report was the first, I believe, which insisted on the importance of looking to local sanitary conditions as a means of protection instead of depending altogether on the vague protection offered by strict quarantine, and this is really the basis on which England has made her stand at all recent conferences and with such satisfactory results.

The next International Conference was held in Constantinople in 1866. The conference came to the conclusion that cholera had always its origin in India and that its extension followed the lines of human intercourse. They were of opinion that quarantine was capable of arresting the disease; such quarantine should be quarantine of observation or quarantine of rigor. Strict quarantine was to be applied to all ships from an infected port with a foul bill of health as well as to any vessel which had cases on board during the voyage although provided with a clean bill; the time fixed was ten days from the time of entering any port to re-commence if any case occurred thereafter. Quarantine of observation was to consist of keeping isolated and under observation for an indefinite time, to be fixed by the local authority, a vessel with crew and passengers with free ventilation but no disinfection. Strict quarantine was defined as the isolation for a fixed time of a ship and persons on board with disinfection of all that might contain the germs of disease. The whole of the cargo was to be landed and the passengers disembarked at a lazaret. In 1873, so far as cholera was concerned, quarantine was officially abandoned by order of the Local Government Board. In 1874 an International Sanitary Conference was held at Vienna, the object being to arrange among the Powers interested compulsory regulations having as their object to bring about a perfect uniformity in the measures to be adopted against the common danger. This conference was the first which in any form gave sanction to the principle of medical inspection taking the place of quarantine and although the decision was not unanimous it obtained the sanction of the majority of the European powers and in the case of the minority some important modifications were made. France was the only one of the great powers who still adhered to quarantine. With so large and powerful a minority, however, it was felt that little could be done and that little had been accomplished.

In the fifteenth report of the medical officer to the Local Government Board Sir Richard Thorne gives an admirable history of these conferences and compares them with the International Sanitary Congress which met in Rome in 1885. He tells us that on no occasion has the value of the adoption of sanitary measures as the principal safeguard against cholera been more prominently recognised than was the case at Rome. In the matter of disinfection it was for the first time distinctly laid down at Rome that it is not necessary to consider articles as infected merely because they come from a country where cholera prevails; that only persons or articles that have actually been soiled by choleraic discharges and articles that have been worn by persons suffering from cholera ought to be subjected to such process; and that in the case of individuals disinfection by means of baths ought alone to be resorted to, fumigation being thus incidentally condemned as useless. In the conclusions of the Technical Commission of the Rome Conference medical inspection, however, finds no place—an omission of a retrograde tendency. The next International Sanitary Conference met at Vienna in 1892. This conference dealt entirely with the question of cholera. It was convened to consider the regulations then existing relative to transit in quarantine by the Suez Canal. The delegates were asked to notify what modifications should be introduced into the constitution of the Sanitary Council of Marine and Quarantine of Egypt and generally the constitution of that council. The conclusions arrived at were subsequently largely modified and considerable alterations and concessions were made, all of which were favourable to this country. Briefly, the following rules were adopted: (1) instead of a prescribed five days' detention of all passengers other than those sick of cholera at Moses' Wells in the case of vessels without a medical man or a disinfecting stove on board the detention will vary according to a sliding scale from forty-eight hours to five days; (2) in the case of a vessel carrying a medical man and a disinfecting stove it is the medical man on board who is to decide what person or persons are to be landed on the ground that they are suffering from cholera—thus there is a quarantine against British subjects suffering from dysentery being landed compulsorily; and (3) in the same class of vessels, whether mail, transport, or other, all landing of healthy persons at Moses' Wells will be avoidable. The conference regarded troopships, from the point of view of the transmission of cholera, to constitute a specially dangerous class.

The next conference was held at Dresden in 1893 to complete, so to speak, the work of the previous conference. It was convened to consider (1) the precautions to be adopted on land and at seaports against cholera; (2) in connexion with them the special conditions affecting the Danube were dealt with also; (3) the organisation of the Board of Health at Constantinople; and (4) the establishment of a board of health at Teheran. The last two points were apparently not raised or discussed. The Convention provided a minimum and a maximum of precaution, the minimum to be obligatory, corresponding closely with the provisions of the cholera regulations in this country. Under the Dresden Convention no ship will be detained in any port when there is a hospital for the sick and all other persons are if possible to be disembarked. The most important difference between minimum and maximum occurs in the treatment of healthy ships coming from cholera infected ports; such ships are always to receive immediate *pratique*. As a minimum of precaution bilge and drinking water must be evacuated and persons landing from such ships may be subjected to medical supervision at home without detention. Healthy ships will not in any case be detained. This was no doubt the most valuable part of the Convention from the point of view of navigation. All goods were freed from restrictions excepting fresh rags and things believed to be "contaminated"—that is, fouled with cholera matters. The measures to be applied to land frontiers were analogous to those for seaports with the important exception that only persons actually suffering from cholera may be detained on land frontiers.

A careful study of the Convention shows that the various provisions were founded on the tacit belief that the poison of cholera comes exclusively from the evacuations of the sick and unlike other disease poisons it becomes innocuous if once thoroughly dried. The conclusions adopted embodied the principles of notification of cases of cholera and aimed at preventing certain unreasonable measures of restriction against countries in which cholera has appeared. The rules as they now stand may be regarded both as defining a maximum and permitting a minimum of restrictions. As regards vessels deemed to be actually infected with cholera the maximum restriction to which they may be subjected will involve a detention of the hitherto healthy passengers for a period not exceeding five days as reckoned from the date of the last occurrence of cholera on board. The minimum of restrictions which is held to be obligatory in the case of vessels actually infected agree with the restrictions which it has long been deemed necessary to apply to such vessels arriving in English ports. This Convention was finally signed by the delegates of Germany, Austria-Hungary, Belgium, France, Great Britain, Italy, Russia, Switzerland, Luxemburg, Montenegro, and the Netherlands. It will last for five years from the date of ratification and be renewed every five years by Tacit Council unless removed by one of the high contracting parties six months before the expiration of this time. Although it does not establish a perfect system it marks an enormous advance.

The next international conference was convened under the auspices of the French Government at Paris in 1894 with a view of devising measures for preventing the spread of cholera by way of the Red Sea and the Persian Gulf. The first point discussed was to the necessity of requiring a medical inspection of all persons going on board a pilgrim ship before embarkation. The conference was assured that this was strictly carried out by Great Britain and British India not only as to cholera but as to all infectious diseases and the proposal to the requirement was unanimously accepted. A second proposal was made relative to the disinfection of all articles deemed "contaminées" or "suspect" in accordance with the terms of the Vienna Convention; and subject to the understanding that the medical officer of health of the port was to be the judge as to what articles came under these definitions the proposition was carried. A third proposal forbidding the embarkation of any passengers deemed to be infected or suspected of being so was also unanimously agreed to. The British delegation opposed the addition of words which would have brought "dysentery" within the scope of the prohibition to embark because for the purposes of the Indian Empire a complete distinction

Digitized by Google

between dysentery and cholera should be maintained and the conference had concern with cholera and not with any other diseases; this was accepted by the Conference. Another proposal was to require an "observation" of five days for pilgrims at the port of departure. Objections were raised on behalf of India and other British colonies and it was decided to grant to each Government the right to act as it saw fit in the matter. At a full plenary meeting of the conference decisions on the following heads were arrived at: (1) sanitary police at the ports of departure; (2) measures to be adopted on board pilgrim ships; (3) sanitary surveillance over pilgrimages in the Red Sea; and (4) surveillance over the pilgrims going by land to Mecca and Medina. In this as in all previous conferences vessels were classified as follows: (*a*) indemns, or ships in which no case of cholera has existed before starting or during the voyage—these receive immediate *pratique* whatever their bill of health; (*b*) suspects, or those ships in which any case of cholera has arisen within seven days; these receive medical visits, are subjected to disinfection, &c., and there is a recommendation (1) as to maintaining the passengers under observation for five days from the date of leaving the port of departure and (2) as to preventing the landing of the crew except for purposes of necessity; and (*c*) "navires infectés," those in which any case of cholera has arisen within seven days before arrival. The sick and the remainder of the passengers are obliged to disembark and to undergo detention under observation for a period of five days at the outside to date from the occurrence of the last case of cholera. Disinfection of linen is also compulsory. This Convention was ratified subsequently by the British Government subject to certain points which bore directly on Indian traffic and pilgrimages from the East.

In 1897 the last international sanitary conference assembled at Venice in connexion with the outbreak of plague in the east and the conference met to settle on an international basis the steps to be taken to prevent, if possible, its spread into Europe. One of the first points to be dealt with was to settle the incubation period for this disease and the period to be adopted for administrative purposes. It was admitted that the incubation period was, as a rule, a comparatively short one—namely, of some three or four days. After much discussion ten days was accepted by a very large majority The work of the conference was divided into two sections; one was to undertake the task of formulating rules for preventing the spread of plague outside Europe and the other for preventing the spread of plague in Europe. When rules came to be formulated for prevention outside Europe the work was considered under several heads such as: (*a*) the action to be taken on land frontiers, (*b*) at infected ports of departure, (*c*) in the Persian Gulf, and (*d*) in the Red Sea. The principle of notification was unanimously adopted. Each Government was to notify to other Governments the existence of plague within their several jurisdictions and at the same time state the measures of prevention which were being carried out to prevent its diffusion. As regards the precautions to be taken on land frontiers it was finally settled that during the prevalence of plague every country had the inherent right to close its land frontiers against traffic. The difficulty which had to be overcome in respect of the Red Sea traffic was the lengthened period of incubation as regards plague compared with cholera. It was decided after much discussion that a healthy vessel might "transit" the Suez Canal and continue its voyage in the Mediterranean during the period of incubation of the disease the prevention of which is in question. This decision was a great advance—more so than was ever admitted at previous conferences. With regard to suspected and infected vessels the conclusions arrived at are in substance those of the Venice Convention of 1892 altered so far as these became necessary in view of the longer incubation period for plague.

Passing on to the conclusions dealing with regulations to be imposed "in Europe" the following were the chief points to be noted. As regards the measures to be adopted at ports of arrival healthy vessels—i.e., those on board which, though they have sailed from an infected port, no plague had occurred—were to have at once free *pratique*, but at the option of the local authority certain measures of disinfection of soiled articles may be required. Suspected vessels—namely, those on board which there has been plague but no fresh cases within twelve days—were to submit to some limited processes of disinfection. It was recommended that the crew and passengers should be subject to surveillance for a period of ten days from the date of the arrival of the vessel. Infected vessels—namely, those on board of which plague was either actually present or on which that disease had occurred within ten days of arrival—were to land their sick. These were to be isolated and other passengers were to be subjected at the discretion of the local authority to "observation" or "surveillance" for a period not to exceed ten days from the date of the occurrence of the last case of plague. The terms "observation" and "surveillance" were for the first time clearly defined, the definition as to the latter stating that under that system passengers are not to be isolated but are to be allowed at once to proceed to their own homes, where they can remain under medical supervision so long as may be deemed necessary by the local authority.

The results of this last conference indicate a great advance on the part of the nationalities represented towards a liberal and truly scientific conception of the means to be adopted by respective Governments for the prevention and control of the infective diseases. Previous conferences upon this matter have indicated a wide divergence between the views held and expressed by the British Government and those of other Powers. This last conference has shown this regrettable divergence of views to be considerably less than it was formerly; in fact, it has demonstrated a well-defined desire on the part of many continental Governments to accept and come into line, as it were, with the well-known and oft-expressed views and practices of the British in regard to the prevention of epidemic diseases from the east and elsewhere.

THE VIS MEDICATRIX NATURÆ IN DISEASE OF THE KIDNEYS.[1]

BY ARTHUR T. WILKINSON, B.A., B.SC., M.D LOND.,
ASSISTANT PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY.

EVERY thoughtful practitioner will acknowledge that when his therapeutic resources are exhausted and he is about to give iodide of potassium, by far the most reliable consultant to be obtained is the vis medicatrix naturæ. Moreover, it is well known that most presidents of societies fall back on this lady in their opening addresses. It would therefore ill become me to pass by so ancient and honourable a practitioner, especially as I believe that both in medical teaching and medical practice we do not give her that pre-eminent position which she deserves. It is true that when we have our little jokes at her expense we suggest that she is a much better physician than surgeon. I have, indeed, seen her amputate a leg that literally had not yielded to a popular ointment and I confess that she did not do it with the neatness or despatch that marked a Lund and a Bradley. Nevertheless, the one object of the surgeon of to-day, after laying aside the knife and closing the breach, is to prevent anyone or anything interfering with this lady doctor of doubtful age into whose hands he commits his case with the utmost confidence. In medicine, where she ought to play the combined *rôle* of colleague and teacher, we are apt to forget her presence. To ignore the fact that she has already been in charge of the case for hours or days when we first approach with our mixtures and tabloids is at least a mistake in medical ethics. To remind you of her existence and her work in one branch of medicine is my object to-day.

The old creative view of nature saw, or endeavoured to find, design in everything. If you will read the works of Ray, who with Boyle and other Fellows of the Royal Society in the seventeenth century led the way to modern science, you will be struck not only with the keenness of his observation and the ingenuity of his theories, but also with the fact that to everything he puts and presses home the question, *Cui bono?* The evolutionary view of nature does not abolish but rather emphasises the legitimacy of this question. It suggests the "how" without taking away the "why." If the principle of utility govern the correspondence of an organism with its environment, surely the re-adjustments within the body in disease will reveal a like law. Moreover, though it may be hard or for the time an

[1] Being the Presidential Address to the Manchester Clinical Society for the session 1895–97.

Digitized by Google

impossible task to ascertain how the readjustments are brought about, the reason why they occur, the *Cui bono?* may be perfectly plain and carry with it important therapeutic suggestions. The limited local movement in pleuritic pain is of complex mechanism, but of the simplest significance and openly counsels enforced rest. Fortunately therapeusis has not always to wait for pathology.

The vis medicatrix naturæ is not simply a power, a vital resistance to disease, but an inherited organised resistance; a series of strategic movements, first offensive, then defensive; a skilled retreat when advance and victory are out of the question. The animal economy has battled for ages with its visible and invisible foes and becoming used to the fight has planned its defence with increasing skill and elaboration. Defeated at the skin or tonsils it shows its second line of defence in the lymphatic glands where phagocytes wrestle with the invaders, whilst other organs manufacture and hurry up reinforcements and prepare and pour out into the blood food and ammunition for the combatants—facts which we as yet only dimly see, and so darkly use our animal extracts and antitoxins. Most of the protective processes are grouped together under the term "symptoms of disease" when they should be regarded as "hereditary treatment." It thus comes about that one of the most important functions of the physician is to determine the therapeutic value of those changes which are too often credited with a purely diagnostic significance or are looked upon as being "part of the disease," for to treat symptoms is at times to neutralise treatment. It is in affections of excretory organs such as the kidneys that the friendly relations existing between the different parts of the body are most evidently displayed and the principle of mutual aid most easily established. Apart from definite tumour, local phenomena, and septic absorption, the presence of disease in the kidneys is revealed (1) by urinary changes—i.e., by excess or deficiency of water, urea, uric acid, and other normal ingredients—and by the presence of abnormal substances such as albumin, blood, casts, renal and pus cells, &c.; and (2) by the constitutional signs of imperfect excretion—namely, high arterial tension, dropsy, cardiac, ocular, and other changes. Many persons exhibit the former—e.g., albuminuria—for long periods without any sign of the latter. This is not at all surprising. We know that one kidney can deal with the nitrogenous excreta of the body if kept within reasonable limits, otherwise nephrectomy would invariably be followed by the results of inadequate renal action. Hence strictly unilateral disease of the kidney is not associated with the signs of renal retention. But we may go further. As long as bilateral disease leaves intact the functional equivalent of one kidney—possibly rather less—there need be no special constitutional discomfort. This is well seen in those lighter renal affections which accompany many febrile diseases, in the earlier stages of the back-working of chronic urethral and prostatic troubles, in early senile failure, and also under another condition to which I must make a passing reference. Scarlatinal dropsy is well known to us—an acute renal failure with vascular, tubal, and interstitial changes, and marked urinary phenomena. That this may end in chronic interstitial nephritis and the patient die several years after with contracted kidneys is also placed beyond doubt. But I have for many years held that we underrate the *rôle* played by scarlet fever in the production of renal fibrosis. Scarlet fever occurs in early life; the history of dropsy often dies with the parents, being quite unknown to the individual concerned. The tubal disturbance subsides, but interstitial processes are left the influence of which on the secreting powers of the kidney are so slight that the knowledge of disease only comes with an attempt at life assurance many years later. For example—(1) a young man in the twenties had mild scarlet fever and dropsy six years ago; his urine before the attack was normal; now it invariably contains albumin; the patient is in robust health and scorns the idea of disease; (2) a man, aged fifty years, leading a very active public life without the aid (?) of alcohol, had scarlet fever thirty years ago; ever since when examined the urine has been found to be albuminous, but it is only within the last year or two that cardio-arterial changes have become definitely manifest. He still enjoys excellent health. These conditions left by scarlet fever may apparently remain *in statu quo* and so account for some cases of lifelong albuminuria without other morbid phenomena. They may, however, progress, and I believe that many otherwise inexplicable cases of interstitial nephritis ending fatally in the twenties, thirties, and forties arise thus. One typical case of my own, in which the retinitis was the sole cause of complaint and led to the diagnosis of the disease, terminated at twenty-four years of age after a latent period of seventeen years. It is to private practitioners, who even in this age of change keep some families under observation for a lifetime, that we look for the more complete elucidation of this question.

In persistent albuminuria the absence of high arterial tension and cardio-arterial changes does not therefore negative the existence of chronic Bright's disease. It merely signifies that the encroachment on the secreting area of the kidneys is as yet limited. If then we find constitutional reactions in persons leading a sober life—i.e., avoiding excess in food and drink—we may reasonably conclude that at least half the secretory power is lost. Turning now to cases that have passed this point I must first remark that the usual result of imperfect excretion is attempted exoretion. That the proper performance of the functions of the kidneys is largely dependent on the blood-pressure is placed beyond doubt. We are therefore prepared to find that increased arterial pressure is the first sign of the contamination of the blood which follows renal failure. The exact cause of this high tension which, with Sir Wm. Broadbent, I believe involves the arterial system from heart to capillaries, is as yet undetermined, but the significance of it—the *cui bono?*—is plain; it is an attempt at excretion. It is physiological rather than pathological, therapeutic rather than morbid. As the late Dr. Mahomed pointed out in his study of scarlatinal dropsy it is a very early phenomenon in acute Bright's disease and may precede marked urinary change. That the high tension is itself the cause of the renal trouble I cannot bring myself to believe; that scarlatinal toxins acting on the cells and glomeruli primarily produce renal inadequacy with high tension, and if not checked lead to further gross morbid changes, seems to me to be a more likely explanation. With the high tension we have the laboured impulse of the distended heart, the impure, prolonged, or reduplicated first sound at the apex and the accentuated second sound at the aortic cartilage and to the left of the cardiac impulse.

The degree to which the system responds to the appeal from the kidneys varies much. A gross public abuse at one time will lead to a riot, at another to a quiet well-organised public protest, or no notice may be taken of the matter at all, the abuse being beyond remedy or the public hopelessly callous or too fully occupied with other concerns. So in renal failure the riot of uræmia may take the place of the well-organised attempt at reform just referred to. But it may be that there is no such response, the task being recognised as hopeless, the vis medicatrix naturæ being ill or ill-developed or the system otherwise occupied as with the febrile process. It is well for us then to bear in mind that at any stage in the defensive operations the system may fail to make a stand, and therefore the absence of high tension, renal dropsy, &c., is occasionally of bad omen. When present we may interpret the high tension as an attempt to stimulate the kidney to action and that I take it is the prime aim of the physician. It may be wise and necessary to promote elimination in other ways, but our first thought is how to re-establish renal excretion. In passing I doubt therefore whether we do well in acute vascular engorgement to omit the cupping of the loins practised by our forefathers. The influence of such measures, applied to the corresponding segment of skin, seems to be independent of any demonstrated anastomosis between the superficial and deep blood-vessels. Constitutionally we usually have recourse to saline diuretics and digitalis. It must, however, be remembered that just as digitalis through accumulation may turn from a remedy to a poison, so this therapeutic high tension may become morbid in quantity. Still, in acute disease attacking a healthy body the chances of evil effects are minimised and under digitalis the heart is less likely to yield to the pressure and the kidney more likely to respond to the appeal.

Should the kidney be placed wholly *hors de combat* the high tension must seek some other outlet. The result is the "acute dropsy" of our forefathers, a term which still appears in the examination papers presented to "practitioners of more than forty years of age." The so-called "mechanical dropsy" of heart failure is often seen in Bright's disease, especially in its later stages, but the acute primary dropsy I now refer to is arterial, not venous, associated with high, not low, vascular tension. It has a different origin and significance. It is an excretion into the body instead of out of the body and therefore a definite

Digitized by Google

therapeutic measure. The products of the metabolism of the master tissues, muscle and nerve, and of the liver accumulate in the blood; they cannot be eliminated by the kidneys; they are therefore turned into the indifferent connective tissues of the body where there is ample accommodation without serious detriment to the system. Hence the eyelids, loose tissue of the scrotum and penis, the skin generally, and the serous cavities are commonly selected. It is an expedient for diluting the poison and providing room in the body for a much larger quantity than the blood itself could hold. Many ounces of urea, not to mention other substances, can thus be stored up. In a case recently under my care, in which the body appeared to be twice its usual size, the liquid in the limbs and cavities yielded 0·5 per cent. of urea and about one-eighth of albumin. Renal dropsy is our friend, not our foe, as long as it does not choose for its habitat a vital spot such as the lungs, the larynx, or the brain. We talk of treating this dropsy, but if by that we mean the mere abstraction of liquid to lessen the swelling we fight our friend. As Sir Grainger Stewart observes, "Perspiration may be followed by marked increase of discomfort." Unless the harmful elements in the dropsical effusion be also withdrawn the letting out of water simply condenses the poison. An ingenious German has suggested that in purely local dropsy the system might be persuaded to drink up the effusion were the patient to abstain from liquids and live on salt food. In Bright's disease this would be a suicidal policy. Hence the recommendation to administer water or some other equally innocent drink in renal dropsy is excellent, as it prevents the concentration of the poison as well as helping to wash out the tubules of the kidney. When purgation and diaphoresis are employed this precaution should always be taken lest the body as well as the kidney be unduly dehydrated.

In the out-patient room at the Manchester Royal Infirmary we have literally forced upon our notice a disease to which little or no reference is made in the text-books. It was, however, most accurately described by Dr. Graham Steell in an excellent paper in the *Medical Chronicle* for 1893 entitled "Heart Failure as a Result of Chronic Alcoholism." There can be no doubt whatever as to the existence and definiteness of this complaint. It is, moreover, so common that the absence of any reference to its frequent occurrence elsewhere leads one to think either that the quality of Manchester beer is not strained, or that Lancashire porters, carters, brewers' labourers, &c., are men of more unbounded stomach than their fellows elsewhere. To attempt a miniature of Dr. Steell's perfect picture would be to mar the original. I will only say that whenever a burly man with a permanent nasal blush, complaining of shortness of breath with more or less cough and occasionally of irregular dropsy, is sent into the examination room and it is found that the area of complete dulness in the cardiac region extends beyond the left vertical nipple line and runs right along the fourth interspace from the sternum to the nipple, not with the half-and-half dulness of health but with a note almost as toneless as that found over the liver, and this without any rheumatic history and usually without bruit, the students instinctively murmur "C_2H_6O." We never interrogate a woman as to alcoholic habits to save the commandments, but we always ask that man how many pints of beer he takes per day and we find that the acknowledged amount ranges from three and four up to twenty, or he says, "Really, sir, I cannot count." Such a patient commonly has a furred tongue with a varying amount of gastric catarrh and in addition to morning sickness the bowels are moved two or three times a day. Unless, however, the nervous system be in the condition which forms the first stage of the journey towards delirium tremens the pulse is not abnormally fast but shows considerable arterial tension. This I have verified by the sphygmograph and I believe it has a very important bearing on the pathology of the complaint. Needless to add this fact did not escape the notice of Dr. Steell. In every case I have seen the bulk of the liquid ingested has been quite as striking an element as the character of the liquid. The latter, however, is etiologically essential as I have not seen the same condition in pure spirit drinkers or "nippers." I believe the complaint is due to a general cardio-arterial stress, to high arterial tension, to a constant overfilling of the blood with material supplying excrementitious matter in excess, and possibly containing one or more substances which specially affect arterio-capillary permeability. No doubt the alcohol plays an important part in the process, probably lowering the nutrition of the cardiac and vascular walls, and thus laying them open to the deleterious action of the high pressure. Still the main element seems to me to be the continuous ingestion of an enormous quantity of liquid much more substantial than water which fails to turn on the renal taps sufficiently to ensure its own rapid excretion. Could the patients start a true diabetes insipidus I have no doubt but that their drinking days might be much prolonged. Such persons drink up to the very moment of their admission to the out-patient room and therefore, in spite of the commencing cardiac failure, by no means rarely exhibit the cardio-vascular stress referred to. In a later stage and after admission to the wards, where the supply of beer is distinctly limited, this etiological factor is not likely to be noted.

Now in this complaint we frequently have dropsy. Sometimes it is typically that of cardiac failure, but the acute dropsy of the earlier stages does not locate itself like cardiac dropsy; it simulates that which is seen in acute renal disease. Only the other day—and not for the first time—I had an experience just such as Dr. Steell describes in his paper. A man came complaining that "his testicles were swelled." We found marked scrotal and penile œdema but hardly a trace of dropsy elsewhere. It looked like a case of Bright's disease; but the urine was highly coloured, acid, specific gravity 1024, and did not contain a trace of albumin. It was simply a case of this peculiar beer disease. Twice within the last three months have I had such cases sent to me as Bright's disease. I have little doubt but that many cases of so-called Bright's disease without albumin belong to the same category.

Albumin may be present in alcoholic heart failure, especially in the later stages, but in these erratic dropsies I have usually found the urine as described. As a rule the forearms and skin of the thorax and loins show marked effusion; the face is involved but the loose tissue of the eyelids not out of proportion to the rest of the face. In one case slight peripheral neuritis may have influenced the distribution of the dropsy, but in the rest I have not noted any nerve lesion. I believe these early effusions have much the same origin and significance as those occurring in Bright's disease; they are excretory dropsies of high tension. That the kidney is functionally at fault there can be no reasonable doubt. The diuresis that should be provoked by the excessive libations is conspicuously absent; the urine is highly coloured, condensed, and scanty; there is increased income, diminished output, and vascular strain. In passing I may observe, as Sir Grainger Stewart points out, that the cough in acute Bright's disease more commonly indicates attempted excretion by the lungs than true bronchitis, so I believe that the cough almost invariably present in beer dropsy has frequently the same significance. Take charge of this disease early enough, cut off the cause, and rest, digitalis, strychnine, and alkaline diuretics soon produce a marvellous change for the better. The free use of alcohol advocated by my colleague, Dr. Steell, I am afraid I cannot endorse. If, however, the above theory of the origin of the "alcoholic heart" be true it is not altogether a case of "similia similibus." Alcohol plays a part, but not the main rôle, in its production. The cardio-arterial condition found in this disease differs materially from that seen in chronic inflammation of the kidneys to which I am about to pass. The changes are distinctly more degenerative and therefore we have much earlier failure of the heart, and in the sequel the more pronounced old-fashioned arterial atheroma. This I am inclined to attribute to the presence of the alcohol.

I have not time to refer to the use made by the system of other excretory areas in its attempt to deal with renal inaction, but must pass on to the cardiac hypertrophy and arterial changes which are the register of chronic high tension and the diuresis which is the *alter ego* of dropsy. Prolonged overfulness of the arterial system produces hypertrophy and dilatation of the heart and arteries as naturally as urethral stricture leads to hypertrophy of the bladder or pyloric obstruction causes hypertrophy and dilatation of the stomach. I believe that the change is at first chiefly muscular and truly conservative and that its degree depends largely on the length of time spent in its production. The vis medicatrix naturæ thus protects the system against undue dilatation whilst securing excretion—an achievement rendered impossible in the beer-drinkers owing to the depressed and deteriorated nutrition of the muscle cells and the checked renal outflow. But let us bear in mind that the only conclusion that

Digitized by Google

can be logically drawn from the presence of these cardio-arterial changes is the existence in the past of prolonged high tension—usually a chronic need for excretion, a chronic attempt at excretion. They do not certify the presence of chronic inflammation of the kidneys; they have a wider significance. In the Transactions of the Royal Medical and Chirurgical Society for 1872 Sir William Gull and Dr. H. G. Sutton attempted to show that the arterio-capillary changes referred to were independent of Bright's disease, purely degenerative in character, and therefore found most commonly in advanced life. This theory has, in my opinion, been rightly discarded. But unless we strain the meaning of the term chronic Bright's disease so as to include simple senile failure, which gives quite different urinary phenomena, we must be prepared to admit that cardio-arterial changes may be renal in origin and yet independent of renal inflammation. All that they indicate is a limited amount of secreting power or secreting tissue, not a certain degree of fibrosis. In chronic interstitial nephritis it is not the increase of fibrous tissue that leads to the affections of the heart and arteries, but the gradual interference with the cells and Malpighian bodies which because of the slowness of its development is compatible with prolonged imperfect excretion short of complete bankruptcy. The same result ensues whether there be pressure from without or gradual primary failure of excretory power on the part of the active tissue itself. The latter occurs in old age, in what we may call the senile kidney, producing many of the constitutional symptoms of Bright's disease without the urinary phenomena. This condition has no more right to be called chronic inflammation of the kidney than senile loss of muscle power has to be called chronic myositis. As I dealt with this subject at some length in a paper read before the Manchester Clinical Society two years ago I will not make further reference to it now. As long, however, as we invariably associate renal high tension and cardio-vascular changes with renal inflammation so long will there be a large residuum of cases occurring apart from anything that one can consistently call Bright's disease. But if we allow that any change which limits renal excretion and habitually leaves in the blood a balance against the kidneys may in course of time bring about the same alterations in the heart and arteries as the coarser inflammatory renal changes so soon shall we rightly interpret many of the troublesome hearts and aching confused heads with vertigo found in old age, ever remembering that senility in body may precede senility in years.

The high tension of chronic Bright's disease and allied states is a means to an end; that end is excretion and the outcome of the attempt is diuresis. Let us not forget that the ordinary constituents of the urine are diuretic and probably help to bring about the high tension in renal failure. After an undiagnosed bladder retention has lasted several days and the urine is eventually drawn off by the catheter we often see as sequel a short diuresis no doubt indicating the retention and therapeutic activity of the urinary excreta within the system. As I have seen two such cases quite recently we perhaps do well to remind ourselves of the extreme latency of chronic urinary retention, the bladder being so tolerant at times that general symptoms, often misinterpreted, may be much more prominent than local distress, and also to remember in connexion with urinary overflow that in bed a very little urine goes a very long way. Everyone is aware that one of the most important signs of improvement in acute Bright's disease with dropsy is the establishment of diuresis. This certainly has no reference to interstitial changes in the kidney and simply shows that the active elements can now respond to the solicitation to excretion. Should the amount of urine return to the normal as soon as the body is cleared of the dropsy the sign is a most encouraging one; but if the diuresis continue long it is plain not that interstitial changes are beginning, though that may be true, but that the recovery of the kidney is as yet only partial and not equal to the needs of the system. It suggests a limit in the amount of active tissue quite as much as a special pathological process. In acute disease diuresis may be regarded as the *alter ego* of dropsy.

In chronic disease diuresis is at the same time a sign of weakness and an evidence of strength. It indicates a deficiency of healthy renal tissue on the one hand, and on the other a cardio-arterial system capable of maintaining the high tension necessary to enable the remaining cells and glomeruli to undertake extra work. Let the heart fail and oliguria, marked albuminuria, and dropsy are the immediate result. That diuresis is limited to those cases developing renal fibrosis I do not believe; there is a systemic as well as a local cause for it. But that it is most marked and most persistent in interstitial nephritis and other forms of renal fibrosis is undoubted. This is probably due, at any rate in part, to the local rise of blood pressure occasioned by the thickening and actual obliteration of so many of the arterioles in the kidney, the gradually diminishing vascular area being supplied by the undiminished renal arteries. Why at times in beer drinking and in old age there is no diuresis is not altogether plain. There may be some inhibition of the secretory elements, but its absence is much more striking in those cases in which the blood contamination is brought about by increased ingestion rather than by pure and simple imperfect elimination. Both conditions give rise to high pressure but the latter more readily leads to diuresis if the renal tissue be in a condition to respond.

In chronic Bright's disease it is the hope and aim of the physician to sustain the relation between the cardio-arterial system and kidneys which secures diuresis, and herein comes the wisdom of the ancients. In the later stages when the arteries lose their elasticity and the heart-muscle its tone high tension becomes a danger and we have to provide against not only cardiac failure but also the possibility of cerebral hæmorrhage, ocular changes, and uræmia. In this connexion it is well for us to remember that even so-called antidotes are far from co-extensive in action and may therefore in therapeusis act as "correctives." Sometimes, indeed, the more detailed the antagonism the more definite and pointed is their combination. In cerebral cases I frequently prescribe strychnine with bromide of potassium and have seen students open their eyes and occasionally their mouths thereat. One of our most popular infirmary mixtures contains dilute hydrocyanic acid and tincture of nux vomica, in spite of the scathing remarks made about such combination in Dr. W. H. Griffiths' useful "Lessons on Prescriptions and the Art of Prescribing." Now in cardiac failure digitalis is so far above all other drugs that if we are obliged to set it aside we are left almost powerless, strophanthus in such cases being a feeble substitute. The liability of digitalis to raise the arterial pressure by increasing the peripheral resistance makes its unqualified use hazardous when the arterioles in places are unfit to bear extra strain. We therefore require something to mitigate this action of the drug whilst upholding or increasing its diuretic power. In my experience iodide of potassium possesses this property, and digitalis may be safely administered in combination with the iodide when it might be dangerous to give it alone. The halogen appears to allow the full cardiac action of digitalis whilst protecting the system against the dangers of undue tension. Anyhow I obtain very satisfactory results from the alliance; prescribed in small repeated doses the quickly-acting iodide no doubt outstrips its slower companion and coöperates with the alkaloids previously ingested. It may be of interest to add that I have found the same combination of drugs on the whole more effective than any other method of treatment in those forms of exophthalmic goitre in which the cardio-arterial phenomena are most prominent. The therapeutic key to the latter disease is, however, yet to be found.

Whilst we promote cardio-arterial competence in Bright's disease we must not fail to read the indications given to us for further treatment. The vis medicatrix naturæ suggests an appeal to the alimentary tract too emphatically for us to overlook it. I well remember an old gentleman in the "seventies," who suffered from the obstruction usual in enlarged prostate, whom I was able to watch closely for several years. Every six to twelve weeks a gradually increasing pulse tension led up to a severe attack of eliminative vomiting lasting from twelve to twenty-four hours or more. The combined emesis and starvation was invariably followed by a wonderful improvement in the pulse and a new lease of life. This went on for years, the vomiting being at times replaced or accompanied by diarrhœa. The patient died from an entirely independent infective bowel inflammation. This action of the vis medicatrix naturæ is plainly set before us for our imitation. I confess I have not hitherto ventured to initiate the movement upwards, but the movement in the other direction falls in so completely with current Lancashire proclivities that I do not hesitate if need be to satisfy the desires of the people to the full. Of the use, however, of calomel, the sulphates

Digitized by Google

and other purgatives and therapeutic measures in Bright's disease I spoke at length in a former paper. Indeed I have now said enough to provoke discussion and that is my main object. There may have been no great novelty in my remarks, but we all look out upon disease from somewhat different standpoints and it does us good from time to time to compare notes so that our views may not become too "cabined, cribbed, confined."

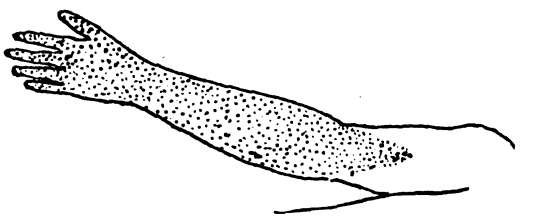
Manchester.

CASES OF

PARALYSIS OF MUSCLES OF THE UPPER EXTREMITY OF PERIPHERAL ORIGIN, WITH SPECIAL REFERENCE TO THEIR CAUSATION.

BY R. T. WILLIAMSON, M.D., M.R.C.P. LOND.,

HONORARY MEDICAL OFFICER TO THE PENDLETON DISPENSARY (SALFORD ROYAL HOSPITAL); MEDICAL REGISTRAR OF THE MANCHESTER ROYAL INFIRMARY.



A NUMBER of cases of paralysis of various muscles of the upper extremity, from lesions of the brachial plexus or branches thereof, have come under my observation which have presented points of considerable interest, either with respect to their causation or to the form of paralysis. The following are abstracts from the notes which I have taken on the cases.

CASE 1. *Obstetrical paralysis; peculiar deformity of the arm.*—A girl, aged thirteen years, came under my care at the Pendleton Dispensary on account of loss of power in the right arm. The mother stated that the right arm had been paralysed from birth. The labour had been a very difficult one and there had been a "cross presentation." No instruments were used, but from the mother's account it is probable that turning had been performed. The child cried all night, and next morning the mother noticed that the right arm was motionless and that there was a swelling about the size of a duck's egg in the right posterior triangle of the neck. Ointment was applied to the swelling and it disappeared in the course of five or six weeks. For a long time the right arm "hung helpless at the side," and then (five or six years ago) gradually assumed its present peculiar flexed position. There had been no mental symptoms; the girl was very intelligent at school and had learned to write with the left hand. The right arm had gradually improved to a slight extent. The legs had never been affected.

On examination the right arm was found to be flexed to a right angle at the elbow. The upper arm was in close apposition to the side, the forearm was supinated, the hand was strongly flexed to the ulnar side, the fingers were semiflexed, and the thumb was markedly adducted, the phalanges of the thumb being in a straight line with the metacarpal bone. The fingers and hand on the right side were bluish, slightly œdematous, and cold; and the whole limb was wasted considerably, but most markedly in the region of the deltoid. The patient could not abduct at the right shoulder. She could flex the elbow quite well, both biceps and supinator longus contracting, but could not extend at that joint. She was unable to pronate the forearm, to extend the fingers, to abduct the thumb, or to perform any movement at the wrist except flexion to the ulnar side to a greater extent. She had the power of increasing the adduction of the thumb and of causing the fingers to become more rigid by slight flexion at the metacarpo-phalangeal joints and slight extension at the other joints. The fingers could also be slightly separated. Beyond adduction no other movement of the thumb could be performed. The muscles paralysed were the right deltoid, the latissimus dorsi, the triceps, the flexors of the fingers, the long muscles of the thumb, the pronators, the extensors of the fingers, the radial extensors, and the radial flexor of the wrist, and the small muscles of the thumb, with the exception of the adductor. The muscles not paralysed were the pectorals, the biceps, the supinator longus, the flexor and extensor ulnaris, the adductor of the thumb, the interossei, the serratus magnus, and the trapezius. On the right hand and forearm and on a triangular area at the front and lower part of the upper arm (as shown in Fig. 1) there was impaired sensation; a very slight touch with the head or the point of a pin was generally not felt. Occasionally over the metacarpal bone of the thumb and on the radial side of the index finger both were felt. There was no affection of the legs or face. The knee-jerks were present. The pupils were equal and reacted to light and accommodation. The palpebral fissures were also equal.

In this case in all probability a lesion of the brachial plexus in the posterior triangle of the neck had occurred at birth. No lesion of any single nerve-root, or of any two nerve roots as they leave the cord, would explain the symptoms. Probably the lesion was very extensive at first, but when the patient came under observation the muscles chiefly paralysed were those supplied by the posterior cord of the brachial plexus and by the median nerve. Both these nerve trunks are composed of fibres derived from the upper and lower divisions of the brachial plexus. The muscles supplied by the outer and inner cords of the plexus (by the musculo-cutaneous and external anterior thoracic, the ulnar, and internal anterior thoracic) were not paralysed. To the above statement there was one exception—i.e., the supinator longus though supplied by the posterior cord was not paralysed.

FIG. 1.

Shaded area indicates region of partial anæsthesia in Case 1.

Combined paralysis of deltoid, biceps, brachialis anticus, and supinator longus; Erb's paralysis of the arm.—This combination of paralysed muscles was first described by Erb,[1] who also pointed out that by careful electrical examination it is possible in many individuals to find a spot (corresponding "to about the point of emergence of the sixth cervical nerve between the scaleni") by the stimulation of which, with the faradaic current, the deltoid, biceps, brachialis anticus, and supinator longus are thrown into contraction. Erb referred the combined paralysis of these muscles to lesion of the sixth cervical nerve root, but many subsequent writers have referred it to the junction of the fifth and sixth cervical nerve roots. This combined paralysis of the above-mentioned muscles may be produced in many ways.

(*a*) It has been caused by tumour growths in the posterior triangle of the neck and by lesions of the cervical nerve roots close to the cord. In the following case a new growth, possibly a syphilitic gumma, in the region of the fifth and sixth nerve roots appears the most probable cause of the paralysis.

CASE 2.—A man, aged thirty-two years, was admitted as an in-patient at the Manchester Royal Infirmary under the care of Dr. Steell (to whose kindness I am indebted for the opportunity of reporting the case). There was a history of neuralgic pains at the back of the head twelve months previously to admission. These disappeared at the end of four weeks, but a few days later he began to suffer from pain at the back of the neck and down the arms. One month after the onset of pain in the neck and arms he first noticed weakness in the right arm; this gradually increased, and in about a week the arm became paralysed, the condition being much the same as on admission. There was a history of gonorrhœa (? syphilis). When first seen at the infirmary the following muscles were found to be paralysed and wasted: the right deltoid, the biceps, the brachialis anticus, and the supinator longus. External rotation of the arm and extension of the elbow were a little impaired. The other muscles of the arm were not affected. There was no definite anæsthesia, but there was a slight impairment of sensation along the radial border of the forearm. No other signs of lesion of the nervous system could be detected. Considerable improvement took place under iodide of potassium and mercurial inunctions.

(*b*) This form of paralysis is sometimes met with in newly-born children. It was first described by Duchenne[2] as *obstetrical paralysis*. Generally the labours have been difficult and some obstetrical operation has been necessary for the delivery of the child, such as turning and subsequent traction, or traction applied to the shoulder, or energetic pressure of the fingers on the neck in the so-called "Prague grip" (Erb), or occasionally the pressure of the forceps.

(*c*) It is often *traumatic*. It has been produced in many cases by falling with the upper extremity outstretched, directed forwards and upwards to prevent the fall; in one case by lifting up a child suddenly to a considerable height by one arm; in another case by dragging a child very rapidly and forcibly by one arm from under a cart to prevent it being run over; in other cases by falls on the shoulder. A number of cases have recently been recorded in which this combined paralysis has followed chloroform or ether narcosis, chiefly in operations on the breast or axilla, and in these cases the arm has been drawn away from the side as far as possible upwards and backwards, and kept fixed in this position for a long time for various reasons. In two cases which I have seen recently the paralysis has been caused by very violent traction on the arm through the limb being entangled in rapidly-rotating machinery.

CASE 3.—A young woman, aged twenty-two years, was admitted into the Manchester Royal Infirmary under the care of Mr. Southam, to whose kindness I am indebted for permission to report the case. On June 5th whilst at work in a cotton mill the left arm was entangled in a rapidly-rotating strap connected with the machinery. The limb was drawn very forcibly upwards and from the side and the body was whirled round, the whole weight bearing on the entangled left arm. Since the accident the patient had not been able to raise the left arm at the shoulder, but had been able to move the fingers and hand. There was some discolouration of the skin with swelling in the left posterior triangle of the neck just above the clavicle for four or five weeks after the accident. On examination the left deltoid,

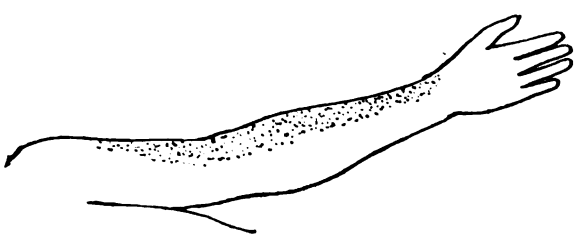

FIG. 2.

Shaded area indicates region of anæsthesia on dorsal surface of hand and in arm in Case 3.

biceps, brachialis anticus, and supinator longus were found to be completely paralysed and markedly atrophied. The muscles of the hand and forearm (with the exception of the supinator longus) were not affected. On the radial border of the forearm (both flexor and extensor surfaces), on the front of the upper arm at its lower part, and on the dorsal

FIG 3.

Shaded area indicates region of anæsthesia on flexor surface of arm in Case 3.

aspect of the thumb and hand at the radial side, is an area of diminished cutaneous sensibility. In this region, shown in Fig. 2, tactile impressions were not felt so well as in other parts of the arm. On this area the touch with a hair was not felt. On the whole of the palmar surface of the hand tactile sensations were felt quite well.

CASE 4.—A boy, aged thirteen years, was admitted as an in-patient at the Manchester Royal Infirmary under the care of Dr. Dreschfeld, to whose kindness I am indebted for permission to mention the case. Nine weeks before admission the patient was pushed by a companion against a large rapidly rotating wheel at the bottom of a shaft of the coal-pit in which he worked as a pit boy. His left hand and coat-sleeve were caught in the wheel, he was carried "off his feet," and whirled round in the air for a few seconds, the whole weight of the body being borne by the left arm. After becoming disentangled from the wheel he found the left arm paralysed. He could move the fingers, but could not perform any movement at the shoulder. On examination the deltoid, biceps, brachialis anticus, and supinator longus, and latissimus dorsi were found to be paralysed on the left side. The first three muscles were also atrophied and gave no reaction to the faradaic current. On examination with the galvanic current—ACC>KCC in the deltoid and supinator longus; in the biceps ACC=KCC. The other muscles of the arm were not affected. There was no anæsthesia.

Now in the majority of the cases in which Erb's paralysis of the arm has been the result of accident the limb has been very forcibly elevated. Often powerful traction has been made on the arm, as when children have been suddenly lifted up or suddenly dragged by one arm; or the arm has been caught in a rotating wheel and very forcibly drawn upwards, as in Cases 3 and 4. Again, in other cases the arm has been drawn upwards and backward forcibly, and kept in that position for a long time during an operation, such as removal of the breast, removal of glands in the axilla, &c. Also, in some cases the paralysis has followed a fall, the arm being extended and raised to "break" the fall. Now in all these cases the position of the arm has been such that the clavicle would be drawn or pushed backward and upward very forcibly, and it appears most probable that the paralysis is caused—at least, in many cases—through compression or laceration of the trunk of the united fifth and sixth nerve roots by the posterior part of the clavicle. From a dissection which I made on the dead subject about twelve years ago I was inclined to regard Erb's paralysis in these traumatic cases as the result of a nipping of the united fifth and sixth cervical nerve roots between the posterior part of the clavicle and the transverse process of the last cervical vertebra, owing to the clavicle being suddenly forced upwards and backwards.[3] At that time I was not aware that this explanation had ever been suggested, but on looking up the literature of the subject a few months ago I found that a similar suggestion had been made by Hoedemaker[4] in 1879. Büdinger[5] refers the cases produced during chloroform narcosis (when the arm is raised and drawn backwards forcibly) to pressure of the upper roots of the brachial plexus between the clavicle and first rib. Gaupp[6] has recently investigated the subject anatomically, especially with reference to paralysis after anæsthetics. He concludes that in these cases the clavicle is rotated on its own axis and is displaced upwards; that it lies across the first rib and compresses the spot where the fifth and sixth cervical nerve roots pass out from between the scaleni.

From a careful dissection which I have recently made with the structures of the cervical region in a much more favourable condition than in my previous dissection I think it is possible that the united trunk of the fifth and sixth cervical nerves might be compressed or lacerated either between the clavicle and the transverse process of the last cervical vertebra or between the clavicle and the first rib when the arm is very forcibly elevated; but by placing the finger in the posterior triangle of the neck in the dead subject in the position of the united fifth and sixth cervical nerves and raising the arm very forcibly I find that it is most tightly nipped between the posterior surface of the clavicle and posterior part of the first rib. The nipping is greatest at a point just in front of the articulation of the first rib with the transverse process of the first dorsal vertebra—i.e., at the posterior part of the rough elevated surface to which the scalenus medius muscle is attached, just in front of the tubercle of the first rib.

Hence I believe that this is the point at which the nerve trunk is compressed or lacerated by the clavicle.

CASE 5. *Paralysis of the inferior roots of the brachial plexus.*—A man, aged sixty years, came under my care at the Pendleton Dispensary in 1894. Twenty-five years previously a heavy beam of wood fell on to the left shoulder whilst he was at work. The shoulder was not dislocated, the patient did not lose consciousness, and there was not very much pain; but immediately after the accident there was loss of power in the left arm, and he was unable to move the fingers. His condition when first seen (1894) was as follows: the fingers of the left hand were semi-flexed; the skin of the hand was "glossy"; there was marked atrophy of the thenar and hypothenar eminences, of the interossei, and of the flexor and extensor muscles of the forearm; whilst the muscles at the radial side of the forearm—i.e., the supinator longus, the long and short extensors of the wrist, and the flexor carpi radialis—were hypertrophied. In the region of the deltoid, triceps, biceps, and pectorales there was no wasting. The fingers and thumb could not be extended, flexed, or otherwise moved. The wrist could be extended but was drawn to the radial side of the forearm. Movements at the elbow and shoulder could be performed quite well. The muscles paralysed were the thenar, hypothenar, interossei, extensor and flexor ulnaris, flexor sublimis and profundus digitorum, extensor communis digitorum, and long extensors of the thumb. The muscles not paralysed were the deltoid, biceps, brachialis anticus, triceps, supinator longus, long and short extensors of the wrist, and flexor carpi radialis. The pupils and palpebral fissures were equal. There was anæsthesia to the touch with the head and point of a pin on the fourth and fifth fingers (dorsal and palmar surfaces, and both ulnar and radial side), and along the ulnar border of the hand and forearm both on the flexor and extensor surfaces, as shown in the diagram (Fig. 4). In other parts of the arm sensation was normal.

FIG. 4.

Shaded area indicates region of anæsthesia of hand and forearm in Case 5.

In the above case it is probable that there had been a lesion of the eighth cervical and first dorsal nerve roots, and some fibres of the seventh cervical also, at the time of the accident.

CASE 6. *Bilateral paralysis of the deltoid.*—A man, aged thirty-two years, was admitted as an in-patient at the Manchester Infirmary on June 22nd, 1889, under the care of the late Dr. Ross, who kindly gave me permission to record this case and also the one following. On Dec. 17th, 1888, the patient fell and broke his right leg. He was admitted as an in-patient at a country hospital in East Lancashire, and kept in bed on his back for one month. Whilst in bed he began to suffer from pain in the shoulders. This continued after he left the hospital and the shoulders began to waste and the skin in the region of the deltoids became numb. Under treatment with electricity the numbness disappeared. On admission to the infirmary both deltoids were completely paralysed and markedly atrophied. The other muscles of the arm and shoulders were not affected, and the patient could perform all the movements of the arms except those depending on the action of the deltoids. There was a small patch of anæsthesia about the size of a sixpence close to the insertion of each deltoid. Apart from these symptoms there were no other signs of any lesion of the nervous system or other organs. The cause of the paralysis in this case was probably a neuritis of the circumflex nerve on each side. These nerves wind round behind the neck of the humerus in their course to the deltoid muscles, and a reference to any anatomical diagrams or to a dissection of the parts will show the possibility of the nerve being injured by pressure of the neck of the humerus in a person kept on his back in one position for a long period, especially if the bed be hard. Osler[7] states that occasionally paralysis of the deltoid arises from a pressure neuritis during an illness. Raymond[8] has published a case in which the deltoids became somewhat suddenly paralysed. The patient had gone to bed quite well and had fallen asleep on his back with the hands clasped behind the neck. Next morning both deltoids were paralysed. In most persons the circumflex nerves have a sinuous course, but in others the course is straight: and observations on the dead subject have shown that when the course is straight the nerve is stretched if the arms are raised and clasped behind the neck in the posture in which Raymond's patient fell asleep; but when the nerve is tortuous no stretching occurs. Raymond regards the paralysis of the deltoids in his case as the result of the bruising and stretching of the circumflex nerves produced by a forced position of the arms in a man whose circumflex nerves ran a straight course instead of the usual sinuous course. In the case which I have recorded it seems probable that owing to the patient being kept for a long period in one position, on his back, the circumflex nerves had been in some way bruised and a neuritis set up, either by pressure on the nerves by the neck of the humerus or by stretching, providing the nerves had a short straight course.

CASE 7. *Paralysis of the serratus magnus, probably the result of violent muscular strain during labour.*—The patient, a woman, aged thirty-four years, was confined on Sept. 25th. The labour was very difficult and finally chloroform was given and the forceps were used. During labour a towel had been attached to the head of the bed; the patient had rested on the right side, with the right shoulder on the bed, and had grasped the towel with the hands. For a long period she had made repeated and very violent traction on the towel. The muscular efforts were so violent that her medical attendant warned her of the danger thereof. On Sept. 28th she suffered from burning pain in the region of the right deltoid. This extended to the scapula and to the middle of the back. There was tenderness in these parts and soon afterwards the patient noticed that the right arm was "too short" when she "tried to reach anything," and a little later it was noticed that the scapula projected. Then the pain disappeared and she had not been troubled with it since. When the patient first came under observation (Jan. 19th) she presented typical signs of paralysis of the right serratus magnus. The other muscles of the arm—the deltoid, trapezius, pectorals, latissimus dorsi, &c., the muscles of the forearm and hand—were not affected. There was no anæsthesia, and apart from the paralysis of the serratus magnus no other signs of disease of the nervous or other systems were detected. Now in this case it seems very probable that the paralysis of the serratus magnus was connected with the very violent and repeated muscular exertion (traction on the towel) during labour. The patient was turned on the right side, the right shoulder was in contact with the bed, and the traction would be made chiefly by the right arm. During these prolonged exertions there would be a repeated gliding of the scapula to and fro over the lateral wall of the thorax, and it appears very probably that thereby a bruising and compression of the nerve to the serratus magnus might be produced and a neuritis set up.

CASE 8. *Unilateral dropped wrist; paralysis of the extensor communis digitorum of syphilitic origin.*—A man, aged twenty-five years, came as a patient to the Pendleton Dispensary about four years ago on account of dropping of the wrist on the right side. Five weeks previously he had begun to suffer from pain along the inner side of the right upper arm and also in the right shoulder. Soon after the onset of the pain loss of power was noticed. The pain was very severe and continued for four weeks. When I first saw the patient the right wrist was found to be "dropped," just as in lead paralysis. Careful examination showed that the extensor communis digitorum was paralysed, but the other muscles of the forearm, the shoulder, and hand, were unaffected. There was no anæsthesia, but there was tenderness along the course of the nerve trunks on the inner side of the upper arm just below the axilla. No tumour growth could be felt however. The left arm was unaffected and there was then no other nerve lesion. There was no

[8] Raymond, Souques and Charcot J. B. Nouvelle Iconographie de la Salpêtrière, No. 1, 1895.

Digitized by Google

blue line on the gums and no indication of lead poisoning. There was no history of alcoholism. The knee-jerks were present and there was nothing to indicate alcoholic neuritis. Further there was no history of injury in the course of the musculo-spiral nerve and no history of any pressure on the arm or in the axilla such as might be produced by falling asleep with the arm over the back of a chair or by the pressure of a crutch. The pain at the inner side of the arm just below the axilla had been severe; it was present a short time before the onset of the paralysis and continued for four weeks. The severe pain and tenderness appeared to indicate a neuritis or some persistent irritative lesion of the musculo-spiral nerve causing loss of function of some of its fibres. At first I was much puzzled as to the exact cause. The paralysis of the extensor communis digitorum was, however, the first of a series of nerve lesions from which the patient has not yet recovered. In the course of a few months the arm recovered completely. But about twelve months later the patient suffered from a complete paraplegia (transverse myelitis) and then for the first time a history of syphilis was obtained. (At first all venereal disease was denied.) The patient had suffered from syphilis several years before the onset of the paralysis of the extensor communis digitorum.

Under anti-syphilitic treatment the patient completely recovered from the paraplegia. About eighteen months later he suffered from right facial paralysis and paralysis of the right third nerve These symptoms in course of time disappeared, but a little later complete ophthalmoplegia developed on the left side, with loss of vision in the left eye (due to optic atrophy). I think there can be no doubt that in this case the paralysis of the extensor communis digitorum was due to a syphilitic lesion (? neuritis or gummatous infiltration) of the musculo-spiral nerve, just below the axilla, and that this lesion had caused loss of function of certain of its fibres only.

Manchester.

A BRIEF ACCOUNT OF TROPICAL ABSCESS OF THE LIVER.

BY C. W. WINDSOR, M.A., M.D. CANTAB.

(Concluded from p. 1449.)

[IN our issue of Dec. 4th we published the first part of Dr. Windsor's paper. The following is the concluding portion.]

Connexion of tropical abscess with dysentery.—In carefully examining any series of cases of tropical abscess of the liver one cannot fail to be struck by the frequency with which dysentery is mentioned. This association may be brought out in three ways: (1) from the history of the patient; (2) from the occurrence of an attack while the patient is suffering from the abscess; and (3) by post-mortem records. This association of the two diseases has long been recognised and much discussion has taken place as to the reality of this connexion. Most of the knowledge of tropical abscess has been derived from India, and looking at the records of these cases quite impartially it is evident that the question of dysentery in some way or other appears very frequently. Dr. Budd was one of the earliest to call attention to the fact that there was considerable importance to be attached to the connexion of dysentery with tropical abscess; his observations were based on cases occurring at the Seamen's Hospital, Greenwich.

In the following statistics the history of the patient plays an important part, and this being so the figures may be objected to on account of the difficulty of getting reliable information. The second source of information is not very fruitful; only one case that I have seen has shown the co-existence of the two affections. As regards post mortem evidence, cases from Murchison's lectures, from Budd's lectures, and cases occurring during the last twenty-seven years at the Seamen's Hospital show numerous examples of the existence of dysenteric lesions occurring in patients who have suffered from tropical abscess; this is perhaps the most trustworthy kind of evidence that is available.

* Under my own observation.

Admitting the above statistics as showing that there is a connexion between the two conditions the question arises, Why should dysentery stand more closely in relation with tropical abscess than other intestinal ulcerations? In India dysentery is of course very common, but then so is enteric fever, and it would be a matter of extreme rarity to see suppuration in the liver as a result of typhoid ulceration, and the same may be said of tuberculous and malignant ulceration. Abscesses in the liver do occur with a certain frequency following injuries and ulcerations in the intestinal tract, but these are almost invariably small and multiple and are part of a general pyæmic infection; while, on the other hand, the abscess following dysentery is usually large, single, and probably contains no infective organisms, and also is not infrequently followed by recovery. So that one is inevitably brought to the conclusion that there must be some peculiarity—some special feature—to account for the frequent connexion between the two diseases. It may be urged that as a certain proportion in a series of cases of tropical abscess show the presence of multiple abscesses why should not all cases, the multiple ones especially, be regarded as pyæmic in nature. To a certain very limited extent this may be true, as it has been suggested that a secondary infection of the liver may take place in addition to the original abscess. Against this view one may bring the facts that the single abscess is more common and that even when the abscesses are multiple there is usually one abscess much larger than the rest, and that it is uncommon to find abscesses multiple in the sense used in pyæmic conditions. And, in addition, the evidence of the sterility of the pus in tropical abscesses, incomplete though it may be, is totally opposed to the idea that tropical abscesses are pyæmic or septic in nature.

An explanation of the connexion of tropical abscess and dysentery would be satisfactory if some factor common to each disease were found, and it was further proved that this factor was the essential cause of the lesions in each disease. But before attempting to settle these questions (which constitute the crux of the whole matter) it is necessary to try to ascertain more definitely the connexion between the two diseases. Three views are held on this point:—(*a*) That supported by Murchison, Abercrombie, Fayrer, and Cayley which, while admitting that there is often some association between dysentery and tropical abscess, says that it is accidental and that there really is no definite relationship between the two, both being due to the climatic conditions. But this theory, although ostensibly admitting that there is a peculiar association between the two conditions, practically denies this by saying that the association is the result or pure coincidence. Nearly every series of statistics is entirely opposed to this view. (*b*) That the dysentery is a sequence of the liver abscess brought about by the contact of irritating bile with the large intestine. This view has met with very little acceptance although Annesley was inclined to support it. The fact that the usual course of events as recorded in histories of cases is the direct opposite of this and also that the whole of the small intestine and biliary passages are unaffected by this supposed irritating bile will go far in disproving this view. (*c*) That dysentery in the majority of cases precedes the abscess is the view strongly supported by Dr. Budd. In most cases where dysentery is mentioned it is usually in the form of preceding attacks, and also in cases examined post mortem scars of dysenteric ulceration are frequently found. Dr. Murchison, although opposed

Digitized by Google

to this view, mentions Waring's series of 300 fatal cases of liver abscess in which 82 gave accounts of antecedent dysentery, and also 204 cases by the same observer in 153 of which intestinal lesions were found. Dr. Moxon expressed the opinion that intestinal lesions would be found in all cases if the intestines were carefully examined. The time elapsing between the occurrence of the dysentery and the development of symptoms of hepatic abscess is very variable but is nearly always covered by twelve months. It is not at all uncommon for patients to be admitted with dysentery who show symptoms of tropical abscess, or an attack of dysentery may come on during convalescence from operation for liver abscess, as in the second case of my own series. Now, in the face of the conflicting views of eminent observers it is not becoming to lay down dogmatically the opinion that dysentery always complicates hepatic abscess and always occurs as an antecedent, but it seems fairly clear that in a large and striking proportion of cases this is the fact.

The next step is to examine the symptoms and physical signs and varieties of dysentery for something definite and characteristic with which to support this opinion. This is a difficult matter, for if one simply relies on the accounts of published cases nothing very definite is found except that the patient gave a history, or showed clinical signs, or gave post-mortem evidence, of dysentery, recent or remote, without any distinguishing features. It seems clear that ordinary dysentery is not more likely to produce an abscess of the liver than other intestinal ulcerations—e.g., in 700 cases of severe dysentery in Millbank Prison not a single case of hepatic abscess was recorded. This fact alone seems to show conclusively that some special feature must be present in the dysentery before a hepatic abscess can be produced. Dysentery is used as a general term to imply frequent motions consisting largely of blood, mucus, and a certain proportion of pus, with tenesmus and tormina. Acute and chronic forms are described, but the distinction between them is arbitrary and is based either upon the severity of the attack, the duration of the symptoms, or the extent of intestinal ulceration, thickening or cicatrisation. In the former there is more active inflammation with infiltration by small cells, necrosis, and ulceration of the solitary follicles which may, however, spread to the adjacent mucous membrane, while in the latter the mucous membrane is thickened and more fibrous in structure, with large irregular areas of ulceration, the whole surface presenting a grey appearance in contrast to the active congestion of acute dysentery. As regards the stools the difference is one of degree only; the frequency is much less in chronic dysentery, although this may be greatly increased during the exacerbations which frequently occur. Blood is more frequent in the acute, and mucus more abundant in the chronic, variety; pus and shreds of necrotic tissue are found in each. The symptoms are less marked but there is greater proportionate wasting in the chronic forms. Diphtheritic dysentery is almost invariably fatal and there is great exaggeration of all the symptoms with delirium, high fever, and acute pain, but it is stated that blood and mucus are not so abundant and that tenesmus is not very common.

There is another form of dysentery which has received much attention lately and on which Councilman and Lafleur and Stockton have written monographs. This variety does not present many variations in symptoms from catarrhal or follicular dysentery but differs essentially in its morbid anatomy and also in showing amœbæ in the stools. From this latter reason it has been called amœbic dysentery. Osler describes the condition of the intestine as being swollen, pale and œdematous, with numerous ulcers of varying shape and depth. There is great undermining of the mucous membrane which may extend into the submucous tissue; the excavations of the mucosa may contain mucus either clear or opalescent. The ordinary signs of purulent inflammation are not present. On examination of the stools there is a striking absence of pus cells but shreds of necrotic tissue are abundant. The characteristic feature is the presence of large numbers of actively moving amœbæ coli. What was said about the mode of examination of the liver pus when searching for these organisms holds good in this case; even the contact with a cold bed-pan is quite sufficient to kill them, when they assume a round shape so that they may be quite easily overlooked. Osler says that this variety of dysentery is often fatal but out of a dozen cases recently under my own observation only one patient has died. Councilman and Lafleur have demonstrated the amœbæ in the floor of the ulcers, in the submucosa and deeper layers of the intestinal wall, and also in the lymphatic vessels. Personally I have never had an opportunity of examining the intestines in a case of amœbic dysentery as the only fatal cases I have seen were in Lascars and Africans upon whom no necropsy is allowed. The amœba coli was first described by Lambl in 1859 and much work upon this subject was done by Kartulis in his study of the endemic dysentery of Egypt. He was enabled to cultivate the amœbæ on straw infusion and noted their multiplication by fission; he injected the cultivated amœbæ in the intestines of dogs and produced dysenteric symptoms, specimens of the amœbæ being subsequently found in the stools. Recently Councilman and Lafleur have written a most exhaustive and apparently convincing monograph with beautiful illustrations to show that this variety of dysentery—which they have called amœbic—is actually due to the amœba coli, and also that this is the form which is so frequently associated with tropical abscess of liver. In fact, they say that the amœba coli is the common cause of a definite variety of dysentery and also of tropical abscess.

I have stated that as far as my own personal experience goes the amœbæ have been found in nearly every case of tropical abscess and in many cases of dysentery and in at least two out of seven cases they have been found in the liver pus and stools from the same case. It thus appears to be proved that there is a special form of dysentery in which amœbæ are constantly present and also that in the pus of certain tropical abscesses of liver the same bodies are found. If the former is to stand in causative relation to the abscess the amœbæ must travel from the intestine to the liver. By what path they do this has not been discovered, but it is highly probable that they are carried in the vessels which drain into the portal vein. This intermediate step in the chain of evidence is not of great importance when it has been shown that by some route or other the organisms do get from the intestine to the liver. It should be mentioned that amœbæ coli have been found in the stools of patients who were not at the time suffering from dysentery. This fact may account for some cases of hepatic abscess in which there is no trace of a dysenteric connexion, for it is quite conceivable that the amœbæ may enter the deeper layers of the mucosa and so into the blood stream without provoking any lesion sufficient to cause symptoms of dysentery. The analogy of the white corpuscle escaping by diapedesis through the blood-vessel wall will help to make this supposition more probable. And also the fact that amœbæ are found in more or less healthy intestines is quite on a level with the discovery of genuine Klebs-Löffler bacilli in the mouths of people who show no signs of diphtheria. So that it will hold good in the case of amœbic dysentery that a place of lowered resistance is necessary before the organisms can produce their effects.

Although the exact path by which the amœbæ reach the liver is obscure it seems fairly clear that they gain access to the human system by means of the drinking-water or by the eating of uncooked vegetables. The drinking-water in those parts of India where the sanitary arrangements are primitive runs great risk of contamination from the dejecta of patients suffering from dysentery. This supposition is much strengthened by the fact that the frequency of dysentery and abscess of the liver in India is diminishing proportionately to the improvement in hygienic conditions generally; the records of the Indian army and gaol population show that abscess of the liver is not so frequent as it was twenty years ago. The improvement in the removal of excreta, in the water-supply, and also, although to a less extent perhaps, in the housing of the native population must contribute to bring about this diminution. At this stage it will be well, perhaps, to mention briefly the etiological factors in the production of tropical abscess which are usually described.

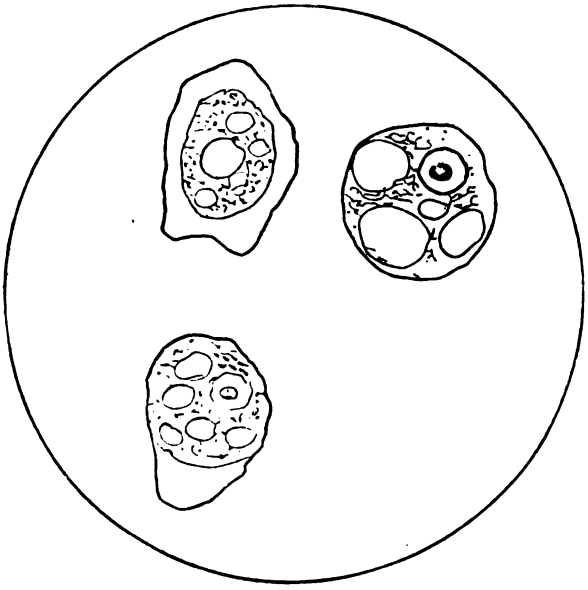
The intense heat of the tropics has been credited with a large share of the etiology of tropical abscess. This applies to India especially; it is rarely that a large single abscess is met with in temperate climates unless the patient has spent some time in hot countries. Intense heat will undoubtedly favour the formation of abscess of the liver but will not by itself account for it as it is a curious fact that tropical abscess is rarely seen in the West Indies or Ceylon where meteorological conditions are found very similar to those of India and also that dysentery is not nearly so common. The influence of sea breezes has been said to bring about this difference. Over indulgence in alcohol undoubtedly is a predisposing cause of all forms of liver trouble, abscess among them. The mortality among publicans is said to be very much higher

Digitized by Google

than among other classes. Among the Indian troops this feature is of importance, while it is interesting to note that tropical abscess is very much rarer in the French colonies in India, where the residents are more abstemious, than in English settlements, showing among other things that careful living has a considerable influence in modifying the tendency to abscess of the liver and also that the tropical heat is not an all-important factor. The lazy sedentary life of most of the European residents in India is said to dispose to abscess, probably acting in conjunction with over-indulgence in rich food and alcoholic beverages. In spite of these causes cases of abscess of the liver are seen in young healthy Europeans who lead healthy abstemious lives and who have only been a short time in India; in this class the liver trouble is more acute and severe than in those who have become acclimatised by long residence in the tropics. All the above mentioned general causes and in addition a chill to the surface of the body when sweating are considered as predisposing to a condition of the liver known as acute hepatitis. It is to this latter cause that most abscesses of the liver are ascribed. In theory this view is quite sound, as in other organs and tissues if the inflammation is acute enough suppuration will result; but it is curious that conditions such as heat, laziness, over-indulgence, &c., which must influence the liver generally should produce only a localised focus of suppuration while the surrounding liver tissue is healthy. Patients supposed to have acute hepatitis show some fever, often high and intermittent with rigors, localised pain and tenderness, with enlargement of the liver and general signs of severe illness and with considerable digestive disturbances, such as constipation, vomiting, varying degrees of jaundice, and loss of appetite. Steps are taken to relieve the acute inflammation—such as local depletion, application of ice, and rest in bed with low diet—and the patient either recovers or presents unmistakable signs of an abscess. The two following cases are quoted from Professor Cayley to show how abscess is supposed to follow acute hepatitis. A man was admitted on Feb. 8th, 1889, with liver enlarged upwards and downwards, with pain, tenderness over the liver, fever, and diarrhœa. No exploration was made and the symptoms were put down to acute hepatitis and the man was invalided home. On April 15th an abscess of the liver burst through the lung and large quantities of pus were expectorated daily. The man died from exhaustion. At the necropsy a shallow, superficial abscess of the liver was found which had burst and converted the whole of the right lung into a huge abscess cavity. In the intestines there were signs of extensive ulceration with numerous small ulcers and thickening of the intestinal coats. Here obviously the symptoms put down to hepatitis were due to the formation and general extension of the abscess of the liver and in all probability had the exploring needle been luckily directed an abscess would have been discovered at the time when the patient was said to have been suffering from hepatitis. The discovery of dysenteric ulceration will be noted. The next case is quoted as "Acute hepatitis following dysentery, going on to abscess formation, one being opened externally by operation and the other bursting into the right lung." The patient had dysentery in September, 1891, and recovered in three weeks. Twelve days after he was re-admitted with symptoms of acute inflammation of the liver—viz., pain, liver enlargement, rigors, fever, and sweating. He was discharged in fourteen days. He was re-admitted with similar symptoms in a few days and in three weeks an abscess was found in the liver and operated on. Another abscess burst through the right lung and after a long, tedious illness the patient recovered. The same arguments as in the preceding case will hold equally good here.

Personally I think that this theory of acute hepatitis has been carried too far and is only a theory with nothing very tangible or objective to support it. The two cases just cited were instanced by Professor Cayley to support his theory, but they do not appear to be very convincing when looked at closely, as all the symptoms quoted as being due to the acute hepatitis are quite compatible with those of abscess of the liver in process of formation and extension and it will be noted that in each case the abscess was large and therefore we may assume took some considerable time to form. So far as I know there is no post-mortem record of acute inflammation of the liver substance brought about by such conditions as those to which the acute hepatitis of tropical climates is said to be due. In pyæmic abscesses of the liver one sees typical acute hepatitis with infiltration of the small round cells, vascular changes, and degenerations of the hepatic cells and all the classical signs of inflammation, including the formation of fibrous tissue. But I have looked in vain for a description of this nature in cases of tropical acute hepatitis. And, moreover, the whole process of the formation of a tropical abscess is different; there is an area of softening (showing degeneration of the hepatic cells—coagulation necrosis) and this area of necrosis breaks down and forms an abscess filled with oil globules, débris of liver tissue, leucocytes, cholesterin, and bile pigments; and above all pyogenic organisms are absent while numerous amœbæ are found. Altogether it appears that the commonly stated factors in the etiology of tropical abscess are somewhat inadequate, although each and all of them may have some contributing effect. On the other hand the presence of the amœbæ coli may be deemed of very much greater importance, and although one cannot absolutely say that this is the essential cause of tropical abscess it does seem probable that it approaches more nearly to a true explanation of the nature of the disease.

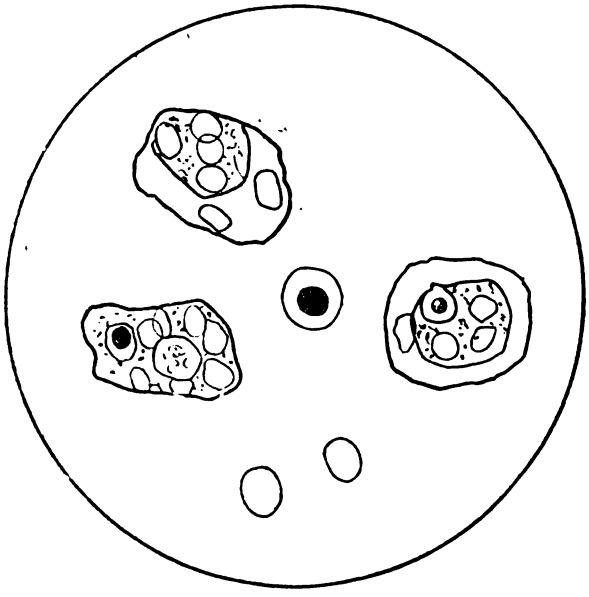
CASES OF ABSCESS OF THE LIVER.



CASE 1.—The patient was a man, aged thirty-seven years, a native of the Channel Islands. He was admitted in a state of collapse. His present illness began six weeks before admission with abdominal pains, cramps, and dysentery, which continued until admission. The pain was of a dull aching character, situated in the right hypochondrium, extending down to the groin. Rigors and rapid loss of flesh had been noticed. On admission the patient was found to be extremely emaciated, with a sallow, earthy complexion, his face bearing a very anxious expression. The abdomen was retracted. At the back there was extension of liver dulness upwards for two inches in the line of the scapula, but no upward extension was noticed in front; downwards there was dulness for two inches below the costal margin. There was bulging of the lower right intercostal spaces and also considerable tenderness on palpation. No œdema of the skin was present. There were signs of pleurisy on the right side. The temperature was high and intermittent. The motions were dysenteric. The liver abscess was diagnosed, but the condition of the patient was too bad for operation. He died a few hours after admission. At the necropsy numerous adhesions of the pleura were found on the right side. Two large, separate abscesses were found in the right lobe of the liver containing yellow pus streaked with blood. Very extensive ulceration of the colon was found, the mucous membrane being much thickened and burrowed in all directions. I must confess that the pus and ulcerated colon were not examined microscopically, as I did not know anything about the amœba coli or its connexion with liver abscess.

CASE 2.—The patient was a Lascar, aged forty-two years. He complained of pain in the right side of the chest, cough, and a feeling of general illness for one week. Eighteen months before admission he had an attack of dysentery. He had been treated in Calcutta Hospital for an attack which lasted twelve days, subsequently to which his health had been fairly good. On admission he was found to be a poorly nourished man suffering from a dull aching pain in the right side with some cough. There were signs of pleural effusion on the right side. The liver was not enlarged downwards and its upper limits could not be accurately made out on account of the fluid in the pleura. There was slight tenderness over the liver. The bowels were regular. The temperature was remittent, between 101·8° and 99° F. There were no rigors, but profuse sweatings at night were noticed. Ten ounces of clear straw-coloured fluid were aspirated from the right pleura. Three weeks after admission, the patient's condition not improving, and the presence of an abscess of the liver being diagnosed, two inches of the seventh rib were resected and the abscess was freely incised, allowing the escape of a large quantity of thick, sweet-smelling, chocolate-coloured pus. Three days after the operation the patient had a sharp attack of dysentery lasting ten days which was cured by rectal irrigation with a weak solution of quinine. The patient was discharged cured four months after admission. Large numbers of amœbæ coli were found in the liver pus and in the stools during the attack of dysentery. The appended diagrams are taken from THE LANCET of May 4th, 1895, where the case is fully reported by Dr. Curnow. I need hardly say that they are diagrammatic, but they are accurate

Digitized by Google



as regards size, having been drawn by the aid of a camera lucida from a specimen seen under a $\frac{1}{12}$ inch objective.

FIG. 1.

Diagrammatic representation of amœbæ showing ectosarc and endosarc. The amœba on the right shows large vacuoles and a pus cell.

FIG. 2.

Amœbæ showing the overlapping of red corpuscles and a free pus cell with two red corpuscles which are drawn rather too large.

CASE 3.—This patient, an African, aged twenty-seven years, complained of pain in the right side of the abdomen and chest of a sharp, shooting, paroxysmal character which had been present for one month. Four months before admission he had a typical attack of dysentery lasting one month, and for the three weeks before admission he had been suffering from a similar attack. He was emaciated. On admission the liver was found to be considerably enlarged downwards, the edge being felt midway between the costal margin and the umbilicus. There was considerable tenderness over the liver. The spleen was enlarged. The urine and stools showed the effects of biliary obstruction although the conjunctivæ were clear. The temperature was high—up to 103° F. —and remittent. There was a small collection of fluid in the right pleura. The liver abscess was diagnosed and was operated on a few days after admission. A portion of the eighth rib was resected and the layers of the pleura were stitched together in order to shut off the pleural cavity, the abscess was opened three days later. About a pint of blood-stained yellowish pus was evacuated; no amœbæ were found although repeated examinations were made, but streptococci were very numerous. The patient made a rapid and uninterrupted recovery.

CASE 4.—This patient, a Scotsman, aged thirty-seven years, complained of a swelling in the upper part of the abdomen. There was absolutely no history of dysentery or chronic diarrhœa. On admission he was found to be an emaciated, sallow-complexioned man, who had been suffering from an aching intermittent pain in the epigastrium for thirteen weeks. Eight weeks before admission the patient first noticed a swelling in the upper part of the abdomen, which was tender and had increased rapidly in size, the skin becoming reddened during the last fortnight. There was a swelling about the size of a baby's head lying midway between the ensiform cartilage and the umbilicus, obviously a large pointing abscess and most probably connected with the liver as the dull percussion note over the swelling was continuous with that over the liver. There was no jaundice. The temperature was high and remittent. There were occasional nocturnal sweatings. The bowels were regular. The chest was quite normal. On operation two pints of reddish-coloured pus were evacuated and the connexion between the swelling and the liver was clearly established. Amœbæ were found only after repeated examination and then not until the fourth day after the abscess had been opened. The patient made a rapid recovery.

CASE 5.—This patient, an Englishman, aged thirty-four years, complained of a sharp, shooting pain in the abdomen, radiating through to the right shoulder, which was so severe as to prevent him from sleeping for one month. An abdominal swelling, tender to the touch, was noticed seventeen days before admission. The bowels usually were constipated. He had lost 2 st. in weight during the last two months. On admission there was a globular swelling lying very nearly in the middle line of the abdomen extending from the ensiform cartilage to the umbilicus and laterally almost to the costal margin on each side. The swelling was tense and elastic and fixed to the liver; fluctuation was obtained and the percussion note was dull, but no fluid thrill was detected. The liver dulness was not increased upwards but downwards and to the right was continuous with that over the swelling. There was no jaundice. The urine was normal. There was slight remittent pyrexia. Three days after admission the swelling was incised and a large quantity of reddish-coloured pus was evacuated, in which, however, no amœbæ were found. Subsequently a few were seen. After the operation the temperature fell to normal and the patient rapidly recovered. There was a somewhat inconclusive history of dysentery a few months previous to admission.

CASE 6.—The patient, a Lascar, aged nineteen years, complained of pain in the right hypochondrium for fifteen days. A history of dysentery could not be elicited. On admission the patient was seen to be fairly well nourished; there was bulging of the right side of the chest, which moved less freely than the left on respiration. There was dulness on the right side from the clavicle to the costal margin in front over the whole of the axillary region, and behind from the spine of the scapula downwards. All the signs of a large collection of fluid in the right pleura, probably pus, were present, the temperature being 103° F. No enlargement of the liver could be made out. There was œdema of the skin of the chest wall on the right side. Twenty-two ounces of chocolate-coloured pus were aspirated from the right pleura. On microscopic examination pus cells, red and white blood corpuscles, and some degenerate liver cells, but no amœbæ, were found. A few days afterwards a large liver abscess was opened after resecting portions of the seventh and eighth ribs and incising the liver substance. Amœbæ, actively moving, were found in the liver pus two days after the operation. The patient died three weeks subsequently from exhaustion. A very limited necropsy was possible, so I had to remove the liver as well as I could through the enlarged operation wound. A large abscess cavity was found in the upper and posterior part of the right lobe which had been opened by the operation; its inner wall was honeycombed and of a dirty yellow appearance, and outside this was a band of hyperæmic liver tissue about half an inch in width. Three small areas of softened liver tissue were found, one in the left and two in the right lobe; they were about the size of a penny on transverse

Digitized by Google

section, yellow in colour, and each was surrounded by a zone of hyperæmic liver tissue. Amœbæ were found in the lining membrane of the main abscess and in the pus from the three patches of softening in the liver. I was not able to examine the intestines.

CASE 7.—The patient, an Irishman, aged twenty-three years, complained of abdominal pains for two months. He gave the following history of dysentery: Eight months before admission his ship—which, by the way, condensed water for her own use—was lying off Java for six weeks. He went on shore once, but did not drink any cold water. As the engines were busy working the cranes loading the ship they could not be spared for the purpose of condensing water, so a quantity was brought off from the land. A few days after drinking this water five men out of a crew of thirty were attacked with dysentery, four very severely, the patient having only a mild attack. The present illness began two months before admission with severe aching pain in the right hypochondrium, constipation, depression of spirits and increasing sallowness of complexion. There was profuse sweating, but there were no rigors. On admission the patient was sallow-faced and rather emaciated; he was suffering from severe abdominal pain. There were slight bulging in the right hypochondrium, considerable tenderness on palpation and œdema of the skin over the lower ribs. The liver was slightly enlarged upwards in the axilla, but downwards it extended almost to the umbilicus, the edge being well defined and the surface smooth. There was no apparent enlargement of the left lobe. The stools were apparently normal, but some amœbæ were found. The temperature was high and remittent. There were no rigors or sweats and no jaundice. The diagnosis of hepatic abscess was confirmed by the exploring needle and subsequently about fifteen ounces of chocolate coloured pus were removed by operation. While opening the abscess both the peritoneum and right pleura were accidentally opened and some pus must have escaped into these cavities before the peritoneum and pleura were stitched up and shut off from the wound. No trouble in the abdomen occurred but the presence of the pneumothorax on the right side considerably delayed recovery by the collapse of the lung which eventually expanded all right. No amœbæ were found in the pus until four days after the operation when they became very numerous. Considerable attention was devoted to ascertaining whether the pus contained organisms, but both cultivation and staining gave negative results. The patient made a rather tedious recovery but was in the best of health on leaving the hospital three months after admission.

Note by Author.—This account of Tropical Abscess of the Liver was written as a thesis for the degree of M D. at Cambridge and I am indebted to Dr. Clifford Allbutt, Regius Professor of Physic in the University, for allowing it to be published. I also wish to express my deep obligation to Dr. Curnow and Dr. John Anderson, physicians to the Seamen's Hospital, Greenwich, for their kind permission to publish and make use of the cases under their care and for much kind help and advice.

Banbury.

TREATMENT OF ACUTE PROLAPSUS ANI.

BY FRANK ELVY, M.R.C.S. ENG., L.R.C.P. LOND.

ACUTE prolapsus ani occurs frequently at childbirth, but as the patient has to keep her bed irrespectively of the anal trouble the condition does not assume so much importance as when the sufferer is an active man of business to whom the time and rest necessary for recovery are serious matters. A succession of these acute cases in many respects similar led me to adopt a treatment which has given encouraging results. The pathology of the condition appears to be a slipping or forcing down of the mucous membrane investing the sphincter and of the mucous membrane immediately above it. Spasm of the sphincters, impeded venous return, and œdema result in the formation of an elastic and exceedingly tender, livid or purple swelling occupying either a portion or the whole of the circumference of the anal aperture. The swelling can be returned above the sphincter without much difficulty by the finger but in the course of a few minutes in many cases the prolapsus has recurred. The application of heat or of cold in the form of an ice compress relieves the discomfort but does not effect a cure or materially alter the size of the swelling. Astringents, either in the form of an ointment or of suppositories, I have found to be useless. Regulation of the bowels and the recumbent position are necessary, but a week often passes before nature brings about recovery.

It is obvious that if the prolapsus could be kept up for a few hours a speedy cure might be anticipated and this led me to employ pads and a T bandage, but it was almost impossible to prevent the descent of a small swelling in this way owing to the awkward situation in the hollow of the buttocks. Under these circumstances and in the absence of thrombosis which would call for incision I have successfully used as a pessary a full-sized Tait's cervical dilator. After replacing the prolapsus with the finger the vulcanite uterine dilator is lubricated and inserted for one inch up the rectum and is retained in position by a collar of dentiste' wax (Stent's composition) supported by cotton wool and a firmly applied T bandage. The pessary not only prevents a descent of the swelling while in position but by its pressure it favours absorption of the œdema and it empties the engorged veins; it should be inserted at night and retained until the following morning. This treatment I have found to bring about a complete cure; there has been no tendency to relapse and the patient has been able to rise and resume his occupation without discomfort. Olive-shaped pewter pessaries have been used for this purpose but they are dependent for their position and retention upon the action of the sphincters which cannot be relied upon in these cases. In the chronic condition of prolapsus ani arising from atony of the levator and sphincter ani muscles much benefit cannot be expected from treatment by pessary.

The following case was the first one treated by me in this way. On June 22nd, 1897, a man complained that for two days he had been in pain from a swelling which he took to be a hæmorrhoid. On examination a tense, bluish, semi-lunar swelling was found occupying the right margin of the anus, the mucous membrane being continuous with the skin at the outer circumference. The patient stated that he had pushed up the swelling repeatedly but that it always returned in a few minutes. This I found to be the case. I then gave him a full-sized Tait's dilator 2¾ in. long and ¾ in. in greatest diameter and conical in shape, for which a collar was made as described above so as to grasp the pessary thus improvised at one inch from its point and prevent it from slipping entirely into the bowel. The patient was directed to return the prolapse when in bed and immediately to insert the pessary well lubricated and supported by a T bandage; he was also strongly advised to remain in bed on the following day until seen by me. Next morning however I received a note to the effect that he felt quite recovered and I heard afterwards that the pessary was worn until 4 A M. when it slipped out but the prolapse did not show any tendency to return and has not done so up to the present time. I have requested Messrs. Fergusson and Co. to make the pessary described above.

Eastbourne.

BRITISH ORTHOPÆDIC SOCIETY.—An ordinary meeting was held on Nov. 5th at the National Orthopædic Hospital, Mr. Muirhead Little being in the chair.—Mr. Reeves exhibited three cases, one of Doubtful Congenital Dislocation of the Left Hip, Double Equino-Varus, and Paralysis of both Groups of Anterior Tibial Muscles. The second case was that of a child suffering from Extreme Equino-Varus on the Left Side with Congenital Absence of the Fibula. The third case was one of Congenital Fracture of the Tibia and Malformation of the Hip.—Dr. Risien Russell, Mr. Tubby, Mr. Little, and Mr. Noble Smith joined in the discussion.—Mr. A. H. Tubby showed a boy, aged nine years, upon whom he had performed Arthrodesis at both Ankles for Flail-like Foot.—Remarks were made upon the case by Mr. Jackson Clarke, Mr. Little, and Mr. Robert Jones.—Mr. Wm. Thomas exhibited a photograph and gave details of a doubtful case of Traumatic Spinal Caries which had been the subject of an action-at-law. He also showed a skiagram representing an Injury to the Epiphyseal Line of the Radius with subsequent Arrest of the Growth of that Bone.—Mr. Jackson Clarke showed the skiagram of a marked case of Flat-foot in a girl about ten years of age.—Mr. Noble Smith read a paper on Spasmodic Wry-neck.—Dr. Risien Russell and other members joined in the discussion which followed.—Mr. Jackson Clarke read a paper and exhibited drawings and skiagrams of cases of Coxa Vara in Infants.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

SARCOMA OF UNDESCENDED TESTICLE REMOVED BY ABDOMINAL SECTION.

BY J. B. PIKE, M.R.C.S. ENG.,
HONORARY SURGEON TO THE LOUGHBOROUGH HOSPITAL AND DISPENSARY.

THE patient was under my care for about ten days before his admission to the Loughborough Hospital. He was suffering from a feverish attack, probably due to chill, and had also some œdema of the right leg. On looking for a cause of the latter symptom I found an abdominal tumour filling the right iliac region and extending beyond the middle line. It was hard, smooth, and freely moveable. The patient was admitted to the Loughborough Hospital on April 8th, 1897, the temperature having fallen to normal, with a view to operation. He was in several respects an abnormal individual, the palate was cleft, both feet were clubbed, and the scrotum contained no testicles. A diagnosis of sarcoma of the retained testicle was made. On April 28th, with the assistance of my colleagues and in the presence of Mr. C. J. Bond, of Leicester, who kindly gave me the benefit of his large experience of abdominal surgery, I opened the abdomen by a median incision. Having ligatured and divided an anterior omental adhesion I attempted to deliver the tumour. The pedicle however being short and the tumour lying with its long axis across that of the abdomen it was necessary to extend the incision for two inches above the umbilicus and as far as possible toward the pubes. The tumour was then brought out by twisting the pedicle in such a way as to bring the long axes of the tumour and the incision into line. The pedicle was ligatured and divided close to the tumour and grasped with vulsellum forceps. It was then again transfixed and tied as low down as possible and divided between the two ligatures. The left testicle was felt, small and apparently healthy, near the inguinal ring. The wound was closed with silkworm gut sutures passed through the whole abdominal wall and no drainage-tube was used. At the end of a week half the sutures were removed and about the tenth day the remainder, the edges of the somewhat large incision being firmly united.

The tumour, which weighed 3 lb. 6 oz., was forwarded the Pathological Museum of the Royal College of Surgeons of England, and for the following description and for a microscopical section which showed typical round-celled sarcoma I am indebted to Mr. Targett, the curator: "It is a very good example of an intra-abdominal retention of a right testis which has become converted into a sarcoma. The growth is round celled in type and is extremely degenerated in the centre. The mesorchium in undescended testicle is usually slender and round. In this specimen it becomes the pedicle of the tumour, which is short, round, and thick. The pedicle appears to be invaded by growth, hence it is probable that the lymphatic glands are already affected. The digital fossa of the testis is distinct, but the globus major and minor are involved in the tumour."

I could find no special directions as to the removal of such tumours in the text-books to which I had access. The operation, of course, resembled the ordinary ovariotomy for solid tumour. The only difference and the chief difficulty lay in the nature of the pedicle. The patient has called upon me since the operation and is at present in good health.

Loughborough.

A CASE OF CONGENITAL ABSENCE OF BOTH PATELLÆ.

BY GERALD S. SAMUELSON, M.D. EDIN.,
HONORARY SURGEON TO THE ARMIDALE AND NEW ENGLAND HOSPITAL, NEW SOUTH WALES.

THIS case I examined in the waiting-room of a railway station some twelve months ago; it was that of a girl aged years. She was unable to walk without assistance, but save for a total absence of both patellæ was a well-grown child. The extensor tendon was thin and narrow and lay free over the anterior aspect of the joint towards its insertion upon the tibial tuberosity; the fingers could be approximated under it as under the tendo Achillis and that of the biceps. Winslow's ligament was weak and slack and was readily distended over the posterior aspect upon hyper-extension of the joint. Keeping the thighs horizontal the legs could be hyper-extended through an angle of some 45° whilst flexion was limited to one of about 25°. There was very little lateral movement or rotation of the legs on their long axes. I know the mother's family, who are vigorous farm-folk; there was no morbid history on the father's side. The mother's pregnancy was uneventful; there was no accoucheur at her confinement; she ascribed her daughter's condition to a "maternal impression" but I forget its nature.

Armidale, New South Wales.

NOTE ON A CASE OF PHTHISIS ENGRAFTED ON MITRAL DISEASE.

BY E. CECIL WILLIAMS, M.B. CANTAB.,
PHYSICIAN IN CHARGE OF OUT-PATIENTS, ROYAL HOSPITAL FOR SICK CHILDREN AND WOMEN, BRISTOL.

IT is held by many that phthisis and mitral disease do not go together, but it is highly probable that cases are not so rare as is generally supposed. Harris and Beale out of 133 post-mortem examinations found that mitral stenosis was present in three cases. The reason for any such antagonism, if it really exists, does not appear obvious unless it can be explained by the pulmonary œdema due to the mitral stenosis acting in the same way as the passive hyperæmia in cases of tuberculous disease of joints. The following are the notes of the case.

A young woman, aged thirty-two years, had rheumatic fever twelve years ago. The patient was fairly well up till six months ago, when her legs began to swell and she had a cough. She was losing her voice and had night sweats and was losing flesh. On examination of the chest there was found to be a slight falling in of both supra-clavicular fossæ and dulness of both apices on percussion. There was a bad entry of air into both apices and there were rhonchi heard both in front and behind. At both bases there were crepitations due to œdema. The heart apex beat in the sixth intercostal space outside the nipple line; the area of cardiac dulness was not increased. There was a low-pitched presystolic murmur heard at the apex and a systolic murmur conducted into the axilla.

It is probable in this case that the heart would have done its work in a satisfactory way for some years if it had not been complicated by the lung disease; it was only during the last six months that it had exhibited any tendency to fail. As the patient has only recently come under observation it is impossible to state exactly when the phthisis first began; she says, however, that she has been failing for the last eighteen months, and it is just possible that the slow progress of the disease may depend on the presence of the mitral disease. The œdema of the legs has disappeared under treatment and there is no albumin in the urine.

Clifton, Bristol.

STARVATION IN CUBA.—Recent reports received by Surgeon-General Weyman, of the Marine Hospital Service, from Sanitary Inspector Brunner note seven deaths in Havana during one week and also an increase in intestinal diseases due to diminished food supplies; he estimates that two-fifths of the total deaths of the city are due to this cause. The place called Los Fosos set aside for the country people sent to Havana is described as a pest-hole. This is a large wooden building sixty feet by fifty feet standing in an enclosure used for storing the carts of the municipality. Of the 500 persons in this building which is *not* a hospital 200 were found lying on the floor sick and dying; all the children under ten years of age were suffering from enteritis or dysentery and their emaciation was appalling; there is an average of ten deaths daily. The civil hospitals are full to overflowing and are refusing patients. One, the Mercedes Hospital which is capable of caring for 200 patients has now 500 within its walls.

SALFORD ROYAL HOSPITAL.

TWO CASES OF GANGRENOUS STRANGULATED HERNIA; RESECTION OF BOWEL; RECOVERY IN ONE CASE.

(Under the care of Mr. EDMUND T. MILNER)

CASES of strangulated hernia which have become gangrenous are fortunately now more rare than in former years, and as intestinal anastomosis by the aid of Murphy's button is still on its trial a record of its application to this class of case may be deemed to be sufficiently interesting for publication.

CASE 1.—A single woman, aged forty years, the subject of phthisis, was admitted into the Salford Royal Hospital on June 23rd, 1897, suffering from a strangulated femoral hernia on the right side. She stated that she had had a rupture for three or four years, that for many months it had not been entirely reduced (? lymphatic glands), but that she had worn a truss over it. There had not been an action of the bowels for seven days, and vomiting had persisted for five days, becoming stercoraceous two or three days before her admission. The patient had rather a languid look, the pulse was intermittent but otherwise fairly good, and the skin of the groin covering the hernia had assumed a greenish-yellow colour. Under chloroform herniotomy was performed. On opening the sac it was found to contain nothing but a loop of small intestine measuring from four to five inches, the middle half of which had sloughed through its entire thickness, but had not actually perforated. After freeing the constriction the loop of gut was drawn down a little, and in order to prevent escape of fæces a double cord passed through the mesentery was divided, and each tube of intestine firmly ligatured just beyond the seat of strangulation, thus securing healthy bowel for these temporary clamps. The herniated bowel was then cut off below the two ligatures and the two stumps of intestine were well washed. The opening into the abdomen was now enlarged by extending the incision upwards for an inch or more, Poupart's ligament of course being divided. A medium sized Murphy's button was selected. The distal (collapsed) stump was dealt with first. Its end with the ligature was re-amputated, the half button was inserted, and its central tube was tied in the lumen of the intestine, just as one would tie a tube in the mouth of a bag. The proximal (distended) stump was similarly treated after emptying and temporarily clamping the intestine a few inches higher up; the two segments of the button were then pressed home. At this stage it was discovered that the cord securing the male half of the button had been inadvertently tied round the spring flange or buffer-segment instead of round the central cylinder, so that the silk cord interfered with a good apposition of the serous surfaces; a continuous Lembert's suture was therefore inserted beyond the line of junction of the approximated buttons, and lastly the edges of the cut mesentery were united. After closing and dressing the wound the patient's stomach was washed out. Feeding with diluted milk (in tablespoonful doses) was commenced six hours after the operation. The button was not passed till the forty-eighth day, the silk cords still retaining remnants of the annular sloughs. The patient made an uninterrupted recovery so far as the operation was concerned, and that in spite of the fact that the phthisis was accompanied by a troublesome cough with the daily expectoration of from six to eight ounces of nummular sputum. She was discharged from hospital on Sept. 23rd, having been kept in the last month on account of her lung trouble.

CASE 2.—A married woman, aged fifty-one years, was admitted on July 7th, 1897, just a fortnight after the first case, suffering from a strangulated inguinal hernia, with gangrene of all structures even to the skin; the egg-shaped rupture occupied the left labium and measured about seven inches by four inches. There was a history of vomiting and obstruction commencing ten days previously, but so reticent had the patient been that it was left for a district nurse to discover a large tumour of the labium, which was already black from gangrene. On admission to hospital the woman was hardly coherent, and her condition was desperate. Under ether the hernial sac was opened, washed out, and the macerated slough of small intestine, measuring ten or twelve inches, removed; the emerging and returning gut were temporarily ligatured as in Case 1, whilst all the gangrenous tissue—sac, skin, &c.—was dissected away. The largest-sized button was chosen and fixed as before, after allowing the distended bowel to empty itself. The woman rallied for a while, but died early the next morning (about six hours after the operation) from exhaustion.

Necropsy.—The post-mortem examination showed very good repair for the time and a healthy peritoneum; the bowel at the seat of resection readily withstood a pressure of from two to three feet of water without leakage.

Remarks by Mr. MILNER.—The introduction of a ready means of establishing intestinal anastomosis has been an important factor in determining the surgery of gangrenous strangulated hernia. It was formerly a common practice in such cases to be content in the first instance with relieving the obstruction, and to hope that the patient's condition would improve before resorting to a secondary operation for the cure of the inevitable fæcal fistula. Experience has shown that only a small proportion of such cases survive to undergo the second operation, for even of those who recover from the immediate effects of prolonged strangulation many gradually succumb to inanition, especially if the alimentary canal has been cut short high up in the small intestine, so that any readier method of restoring the continuity of the alimentary canal is welcomed which can be effected at the time of the herniotomy, and especially if the operation can be accomplished without skilled help. During both the above operations the senior house surgeon happened to be out, and the junior house surgeon, Dr. Arnison, was fully occupied, especially in the second case, in giving the anæsthetic, so that I had to do the operations single-handed but for some valuable help from the nurses. This was my reason for departing from the more usual method of securing the buttons and adopting what appeared to me at the time the quickest though perhaps more clumsy plan. Still, under ordinary circumstances I would not recommend it, as in both cases I found it necessary to supplement the operation with Lembert's sutures, though in the second case merely to cover in a little exposed mucous membrane near the mesentery. The temporary ligaturing of the bowel I found of great assistance; it enabled me to cut away rapidly the gangrenous portions and to cleanse thoroughly the parts before enlarging the abdominal wound, thus minimising the risk of infecting the peritoneum. In the successful case it is interesting to note that the intermission of the pulse—probably due to toxins—disappeared about the third day. The healing of Poupart's ligament has resulted in a thoroughly firm and sound cicatrix, and the bowels, though at first rather constipated, have since become normal.

ROYAL INFIRMARY, NEWCASTLE-UPON-TYNE.

A SUCCESSFUL CASE OF PYLORECTOMY.

(Under the care of Dr. G. H. HUMB.)

THE operation of resection of the pyloric end of the stomach for malignant disease must always remain one of the most severe operations in surgery. The amount of shock is great and much care is required to bring accurately together the very unequal apertures of the stomach and the duodenum. The recorded mortality is high as might have been expected. Winslow[1] collected 55 cases and of these 41 died from the effects of the operation, a mortality of 74·5 per cent.; Bramer[2] collected 72 cases of pyloroctomy and 55 died, a death-rate of 76·3 per cent.; in Eiselsberg's list of 19 cases from Billroth's clinic from 1885 to 1889 there were 10 deaths; this is equal to a mortality of 52 per cent.[3] Even should the patient survive the immediate dangers of the operation the prospect of a perfect recovery is exceedingly small. In a large majority of the cases recurrence occurs after a few

Digitized by Google

months or freedom from return of the disease may be more prolonged, but in almost every case recurrence occurs sooner or later. In Wölfler's case the patient had no digestive disturbance for five years, but died five and a quarter years after the operation.[4] We published in THE LANCET about two years ago[5] an account of the death of a patient on whom pylorectomy had been performed nearly five and a quarter years previously; the case had been operated on by Mr. Rawdon, of Liverpool; recurrence was shown by hæmatemesis which occurred three and a half years after the operation. The most satisfactory case of all is a patient under the care of Kocher. She is still alive and in good health with a very good appetite and digestion and now more than nine years have elapsed since pylorectomy was performed for undoubted carcinoma.[6] This is the only recorded case which can be described as probably cured. The following case is well worthy of record, for in operations of such importance as pylorectomy each case should be published whether successful or not, and especially is this case of value as from the great mobility of the pylorus the risk of recurrence is probably not so great as usual. For the notes of the case we are indebted to Mr. John Clay, the surgical registrar.

A woman, aged forty-nine years, was admitted into the Royal Infirmary, Newcastle-upon-Tyne, on June 28th, 1897, giving the following history. A year before admission she began to feel weak and tired and six months later she commenced to be troubled with severe aching pain in the epigastric region, the pain being constant and worse at night and after food. She vomited about once a month, but the vomit was not frothy or large in quantity. On admission she was thin but not emaciated or anæmic, but her nights were much disturbed by the severe pain in the epigastric region. A round hard tumour could be felt in the epigastric region; it was about the size of an egg but not tender, although handling increased the after pain. The tumour was very moveable, it being possible to push it well over to the left of the middle line.

An operation was performed on June 30th. The anæsthetic used was chloroform. After a median incision from the ensiform cartilage to the umbilicus had been made the moveable tumour felt through the parietes was found to be the pylorus which was with ease brought out through the median incision and was packed round with gauze, its upper and lower borders being separated from the lesser and greater omenta respectively; it was impossible to get between the right gastro-epiploic artery and the stomach and the artery had in consequence to be divided. A small hard gland was found in the free border of the lesser omentum. The stomach was divided, the cut end being held in the fingers of an assistant. The duodenum was ligatured by an indiarubber tube and divided; the cut surfaces were very vascular. The posterior parts of the duodenum and the stomach were united with interrupted sutures of catgut passing through all the coats as recommended by Mr. Rutherford Morison, the anterior wall of the duodenum was then divided longitudinally as is done in pyloroplasty, making a larger free edge to suture to the stomach. The front parts of the stomach and the duodenum were then united by interrupted catgut sutures; the stomach having a larger free edge than the duodenum a portion of the free edge of the stomach had to be sutured in a line at right angles to the junction of the duodenum and the stomach. The catgut sutures were then buried by Lembert's sutures of fine silk and the abdominal wound was closed.

The patient made an uninterrupted recovery and was discharged from the infirmary on July 28th feeling well and being able to eat ordinary food. When she was seen on Nov. 1st she looked very well, she had had no pain, and her food was digested without discomfort.

GOVERNMENT CIVIL HOSPITAL, HONG-KONG.

A CASE OF ABDOMINAL HYSTERECTOMY FOR MALIGNANT DISEASE.

(Under the care of Dr. J. M. ATKINSON.)

IN the majority of the cases of carcinoma of the uterus the vaginal method of hysterectomy is to be preferred and most statistics on the subject show a much lower mortality for this operation than for abdominal hysterectomy, but in not a few of the cases the higher operation is the only one available because it is not possible to pull down the uterus satisfactorily. There is but little to choose between the operations so far as the chance of recurrence is concerned.

A woman, aged forty years, was admitted on July 21st 1897, to the Government Civil Hospital, Hong-Kong, suffering from malignant disease involving the cervix and the posterior part of the vagina. The patient was married when she was eighteen years of age, and had had five children born alive and three premature confinements, the last of which occurred on May 23rd in this year, and was complicated with a placenta prævia. For the last eight months she had been losing weight, and had suffered from occasional attacks of menorrhagia; latterly the discharge, in addition to being sanguineous, was particularly offensive. Examination by the vagina showed the presence of a hard mass growing from the cervix uteri and extending backwards involving the posterior wall of the vagina. The growth sprouted into the vagina, the outgrowths being very soft, breaking down with the least pressure and bleeding profusely. As the uterus was fixed, and it was impossible to draw down the cervix with volsella, the abdominal operation was decided upon.

The operation was performed on Aug. 8th, Dr. Jordan, Mr. Bell and Dr. Swan assisting. Chloroform was the anæsthetic used. An incision was made in the middle line some four inches in length, this was prolonged upwards to allow of more room. The uterus was drawn out of the abdomen. After ligaturing the ovarian vessels, the pampiniform plexus, and the uterine vessels the broad ligament was divided along the brim of the pelvis; this having been completed on both sides the peritoneum was incised transversely in the vesico-uterine fold and reflected backwards for a short distance on the uterus; the peritoneum was incised similarly in the recto-uterine fold. The whole of the uterus with its appendages and the growth were then removed by incising the vagina in front of the external os. The growth was found to involve the posterior wall of the vagina and the tissues round about; this was removed as far as possible by dissection. After securing all the bleeding points the cut surfaces of the peritoneum were brought together by fine sutures, and after carefully sponging and cleansing the peritoneum the abdominal wound was closed, the vagina being packed with iodoform wool.

As the patient was somewhat collapsed three minims of the hypodermic solution of strychnine were injected hypodermically, and in the evening a sixth of a grain of morphia was injected. She passed a fair night and there was no vomiting. On the 9th the temperature at 6 A.M. was 100·4° F. and the pulse was 118; at 4 P.M. the temperature was 101°; and at 8 P.M. 100·4°, the pulse being 126. As there was considerable pain a sixth of a grain of morphia was given. On the 10th the temperature at 8 A.M. was 100·6°, at 6 P.M. 99·8°, and at 12 midnight 99°. The abdominal wound had practically united by first intention. The temperature kept below 100° until the evening of the 13th, when it rose to 101·8°, the cause being a stitch abscess in the upper part of the abdominal wound. On removing two stitches the tension was relieved and the temperature next morning was 100°. She now steadily improved until the 20th, when her temperature was normal all day. She was practically convalescent by the 26th, but was detained in the hospital for a few weeks longer on account of an attack of malarial fever. She was finally discharged on Sept. 26th, having put on 3 lb. in weight during the last two weeks.

Remarks by Dr. ATKINSON.—I have recorded this case as it shows what can be done in the way of abdominal surgery even in the middle of a trying summer in the tropics. This was evidently a case of rapidly growing medullary carcinoma, as nothing was observed at the last confinement in May. On examining the uterus after removal the growth was found to have extended to the body of that organ.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Experimental Atrophy of the Kidneys—Human and Equine Glanders—Negative Action of Sewer Air in Raising the Toxicity of Non-Virulent Diphtheria Bacilli.—Cyst of Cæcum—Pleomorphism of the Colon Bacillus.—Calcification of the Mitral and Aortic Orifices.—Exhibition of Specimens.

A MEETING of this society was held on Dec. 7th Dr. J F. PAYNE, the President, being in the chair.

Dr. J. ROSE BRADFORD read a preliminary note on Experimental Atrophy of the Kidney caused by Obstruction of the Ureter. The experiments were performed on dogs. The ureter was ligatured in two places near the bladder through an incision in the groin and divided between the ligatures. After an interval varying from ten to forty days the distended ureter was exposed, brought to the surface of the abdominal wall, sutured to the skin and drained, about from 50 to 70 c.c. of fluid being evacuated corresponding to a distension of the kidney to the size of the fist. The fluid was clear in nine cases and purulent in three. The animals were killed by prussic acid at periods varying from seven to fifty days after the second operation, the kidneys being removed at once and placed in Muller's fluid. On examining them it was found that atrophy had ensued. The kidney had resumed its normal shape, but was only one-third or one-fourth of its normal size. The naked-eye appearance of the cortex and medulla was so little altered that it was difficult to believe that it had ever been dilated to the extent that was proved by the amount of fluid which escaped when the ureter was drained. The length of time during which drainage was allowed to go on before the animal was killed did not appear to have much influence on the amount of atrophy. The exact composition of the fluid which drained off was not yet thoroughly worked out. Microscopically the kidneys showed no general cirrhosis. Some of the tubules had disappeared and in others the epithelium had in part been shed, but the main cause of the atrophy was the crowding together of the tubules and more especially the small size of the cells lining them. These cells had lost all their granules, their protoplasm being clear and glass-like, while the nuclei stained well. The appearances were those of "resting cells."—Mr. T. W. LAWRENCE gave a lantern demonstration of photographs showing the microscopic changes produced in the renal structure in the dogs experimented on.

Dr. F. W. ANDREWES and Mr. JAMES BERRY showed the Nose and Neighbouring Parts and also the Lungs from a case of Human Glanders. The patient from whom they were taken was a man who was not known to have had anything to do with horses. Ten days before death he noticed a swelling of one eyelid which was supposed to be an ordinary cellulitis. The day before death profuse discharge from the nose occurred. In the mucous membrane of the nose and antrum there was a number of small yellow tubercles, some of which had coalesced and softened, leaving an ulcerated surface. There was some ulceration in addition on the lips and palate. There were also the scars of old syphilitic mischief on the palate. The lungs were studded with small yellow nodules partly on the surface, partly in the deeper parts, not unlike multiple pyæmic abscesses, but harder and not breaking down in the centre. There were a few small round tubercles in the skin in front of the shoulder. Cover-glass preparations showed the presence of the glanders bacillus and this was confirmed by cultures and by the demonstration of the bacillus in the diseased tissues.

Dr. JOHN MCFADYEAN showed recent specimens and lantern slides illustrating the characteristic appearances of Equine Glanders. He described fully the appearances of the lungs and said that in the majority of cases the deposit was in the form of masses which went by the name of "glanders tubercles," which differed from true tubercles in being less numerous and harder to the touch. On section they were often grey and translucent, with a whitish opaque centre and were usually surrounded by a hæmorrhagic zone. The lung tissue between the nodules was often absolutely normal.—Dr. BRADFORD asked whether there were any abscesses in the muscles in Mr. Berry's case. Some years ago there were three cases admitted into University College Hospital and in those there were multiple abscesses in the centre of the muscles.—Mr. BERRY, in reply, said that no muscular abscesses were found, nor had softening taken place in any of the other nodules.

Mr. S. G. SHATTOCK read a paper on the Negative Action of Sewer Air in Raising the Toxicity of Non-Virulent Diphtheria Bacilli. He remarked that it had at different times been surmised that some causal relationship subsisted between defective drainage and outbreaks of diphtheria—i.e., that the inhalation of sewer air determined the occurrence of diphtheria. By some it had been thought enough in refutation of such a view to point out that the diphtheria bacillus could not be conveyed in sewer air seeing that bacilli are not disengaged by evaporation from the fluids in which they are growing. What is conceivable, however, is that a non-virulent diphtheria bacillus such as is present in the throat of many individuals might in consequence of the inhalation of sewer air regain its virulence and become the cause of a diphtheritic lesion which except for this factor would not have arisen. Having for some time had this possibility in mind Mr. Shattock had put it to the test and though the results were negative they might be of interest, though he did not think they exhausted this question. Two samples of diphtheria bacilli were tested. They were derived from cultures made by Dr. F. W. Andrewes, who had examined them with Professor Kanthack, and they presented the morphological characters of diphtheria bacilli, although upon guinea-pigs their subcutaneous injection was followed by local swelling only. Mr. Shattock had, moreover, tested them on 1 per cent. glucose broth, to which they imparted in twenty-four hours a characteristic acid reaction. The cases from which they came presented clinically the signs of ordinary sore-throat. Before commencing the experiment Mr. Shattock had for several days carried the bacilli from broth tube to broth tube (prepared from fermented veal) in order that any toxicity they possessed might be raised to its acme. When tested upon guinea-pigs they were found to be still non-virulent. The method of experiment consisted in growing the bacilli in Duclaux flasks of broth over the surface of which medium sewer air was continuously and slowly drawn by means of a water pump. The flasks were renewed about every three days for several weeks, the inoculation being made from each pair to its two successors. The main sewer was found to be so well ventilated that no "sewer air" could be got from it. It was necessary therefore to improvise a badly drained sewer and this was done by drawing air over sewage stored in two tanks and afterwards through sewage in a capacious Wolff's bottle in the hot room itself; the tube from the latter was conducted to the Duclaux flasks. From time to time fæces were added to the sewage so that a continuous supply of fæcal air was thus obtained. This addition had the effect of considerably retarding the growth of the bacilli for some days. One bacillus was cultivated in this manner for two months, the other for five weeks. From the first flask in each case after growth was pronounced a test-tube of broth was inoculated and twenty-four hours later the cultures in the tube were tested by means of 2 c c. injections given subcutaneously to guinea-pigs. The bacilli had remained non-virulent.

Mr. C. A. MORTON showed a specimen of a Cyst of the Cæcum. The cyst was attached at the opening of the vermiform appendix with which it communicated by a very fine aperture. The appendix was adherent to the cæcum and its walls were thickened. The cyst and the appendix were removed. It was then found that the cyst had a thick muscular wall and contained a rich amber-coloured jelly and was lined by a definite membrane on which were some calcareous plates. Mr. Morton found it difficult to account for the formation of the cyst as it was not covered by the mucous membrane of the cæcum as would have been the case if it had been due to an obstruction of the orifice of the appendix.

Mr. H. C. HASLAM read a paper on Pleomorphism of the Colon Bacillus in which he endeavoured to find some of the causes of the variations in size and shape which occur so extensively in different cultures of the bacillus coli communis. He grew the bacillus on certain pure substances, on peptone, albumin, glucose with only a minute amount of nitrogenous matter, ammonium tartrate, and leucin. He found that the organism varied in size, shape, and structure according to its medium. On proteid the bacillus was pleomorphic, of length generally between 1 μ and 2 μ. In structure the organism was not uniform, the ends of the bacillus appearing darker and slightly granular while the body was translucent and homogeneous, and these ends

Digitized by Google

stained deeper than the bodies. This appearance was always associated with alkalinity of the medium and in neutral or acid media is far less marked. On glucose short coccus-like forms were in the majority; on ammonium tartrate, a highly nitrogenous material, the forms were longer, varying from 2·5 μ to 1 μ. On leucin, a substance containing a less amount of nitrogen, the forms were smaller again. And if in a glucose solution the nitrogenous matter was increased an increase of longer forms took place.

Dr. F. PARKES WEBER showed a Heart in which the aortic orifice was stenosed and rigid from calcification. The mitral valves were likewise thickened and calcified. There was great hypertrophy (the weight was twenty-four ounces) chiefly of the left ventricle. The main interest in the case depended on the physical signs observed during life. The fact that the cardiac dulness reached higher up on the right than on the left of the sternum suggested aneurysm, but in other respects the clinical features of the case were those of an extreme instance of "pure aortic stenosis" associated with persistent bradycardia and more or less permanent dyspnœa with occasional syncopal attacks. The systolic murmur was loudest over the second and third intercostal spaces to the right of the sternum; it could be easily heard without a stethoscope if the ear were placed within an inch or two of the chest wall and was accompanied by a harsh thrill and slight (non-expansile) pulsation. The frequency of the heart's action remained between 44 and 48 beats in the minute, unaltered by exercise or by drugs. The patient, who had lived an active life, had suffered from syphilis when seventeen years of age, but had never had rheumatic fever. He had been told that he had heart disease several years ago, but had enjoyed tolerable health till the year preceding that of his death. Dropsy and signs of increasing cardiac failure appeared at the last. In one of the coronary veins was an adherent, red, comparatively recent thrombus.—The PRESIDENT remarked that he had seen two cases in which the murmur was audible at some distance from the bed. In neither was there an aneurysm.

The following card specimens were exhibited by Mr. CECIL F. BEADLES: (1) Primary Sarcoma of the Liver; and (2) Tumour of the Suprarenal Capsules.

OBSTETRICAL SOCIETY OF LONDON.

Pyometra complicating Cancer of the Cervix.—Obstruction of Labour by Ovarian Tumours in the Pelvis.—Exhibition of Specimens.

A MEETING of this society was held on Dec. 1st, Dr. C. J. CULLINGWORTH, President, being in the chair.

Dr. WALTER W. H. TATE read a paper on three cases of Pyometra complicating Cancer of the Cervix. According to Bürkle's statistics, compiled from German operators, pyometra occurred as a complication of cancer of the cervix in 17 out of a total of 273 cases, giving a percentage of 6·2. Dr. Tate had met with this condition in 3 out of 28 cases of vaginal hysterectomy for cancer of the cervix. Case 1.—The patient was a widow, aged sixty years, who had had nine children. The menopause occurred at the age of forty-five years. There was a history of slight discharge, occasionally bloodstained, for two years, which had become offensive in character for the last six months. The cervix was greatly enlarged and infiltrated with cancer which formed a large mass filling the upper part of the vagina. Vaginal hysterectomy was performed on July 9th, 1897; the uterus contained three or four ounces of most fœtid pus. The patient recovered. Case 2.—This patient was a married woman, aged sixty-one years, who had had nine children. The menopause occurred at the age of forty-five years. There was a history of slight blood-stained vaginal discharge for nine months, more profuse for three weeks before admission to hospital. The cervix was hard and infiltrated with cancer; there was a shallow ulcer around the external os. The uterus was not apparently enlarged. Vaginal hysterectomy was performed on July 30th, 1897; the cervical canal was practically occluded and the uterus distended into a sac which contained about three ounces of very fœtid pus. The patient recovered. Case 3.—This patient was a married woman, aged sixty-five years, who had had seven children. The menopause occurred at the age of forty-one years. There was occasional blood-stained discharge for four years at intervals of a fortnight; for five weeks before admission the discharge was purulent and offensive. The cervix was enlarged and very hard, with an irregular ulcerated surface towards the vagina which bled very freely. On examination the body of the uterus was found to be enlarged and elastic, obviously containing fluid. Vaginal hysterectomy was performed on Aug. 26th, 1897. The uterus contained three and a quarter ounces of very fœtid pus. The patient recovered.—Dr. LEWERS said he had had sixty-seven radical operations for cancer of the uterus; excluding ten of these which were cases of cancer of the body of the uterus there remained fifty-seven operations for cancer of the cervix. Among these he had met with two examples of pyometra, the larger of which he had shown before the society. In that case he removed the whole uterus not on account of the pyometra but because the growth had spread so high that it seemed easier to get well beyond it by complete hysterectomy.—Dr. AMAND ROUTH thought that the fact brought out so well by Dr. Tate that cases of pyometra could exist without stenosis of the cervix was of great importance and enabled one to explain those cases of hydrometra and gushes of large quantities of clear, straw-coloured fluid which were not uncommon after the menopause. Many of such cases had no obstruction of the cervix and no tubal swelling was present. With regard to the two cases of vaginal hysterectomy where the surrounding tissues were already apparently involved he said it was impossible to be sure that such indurations were malignant and not inflammatory.—After remarks by Dr. LEA and Dr. HERMAN, Dr. TATE replied.

Dr. R. G. MCKERRON read a paper on the Obstruction of Labour by Ovarian Tumours in the Pelvis. This paper dealt only with those cases where the ovarian tumour occupied the pelvis during labour. One hundred and eighty-three instances of this complication had been collected. These were arranged in nine tables according to the treatment adopted. Two unpublished cases were detailed. A brief reference was then made to the various publications on this subject. It was pointed out that there still existed as evidenced in the more recent publications a divergence of opinion as to the most satisfactory treatment. The results of the various methods were analysed. To avoid the erroneous deductions to which mere statistical enumerations were liable account was taken where the data permitted of the character of the tumour, of the duration of labour, &c., points which would be found noted in the tables. Attention was directed to a few features of interest in the clinical histories of the cases. Practical observations were made on the various methods of treatment based on a study of the cases and of the literature of the subject. Reposition should in all cases be first attempted; where it failed a selection, according to circumstances, must be made from the following operative measures: puncture, Cæsarean section, abdominal or vaginal ovariotomy. The indications for each of these methods were given. Dr. McKerron concluded with a brief reference to the after treatment in those cases where the tumour had not been removed during labour.

The discussion on the paper was adjourned.

The following specimens were exhibited:—

Dr. MCKERRON (for Dr. WILLIAM STEPHENSON): A Peculiar Mucous Polypus of the Cervix Uteri.

Dr. MACNAUGHTON JONES: (1) Notes of a case of a Double Pyosalpinx with Enlarged Bladder; and (2) Uterine Fibroids.

Dr. DAUBER: Carcinoma of the Body of a Uterus, also Affected with Multiple Fibromyomata, removed by Abdominal Pan-Hysterectomy.

Dr. ARNOLD LEA: Microscopic Sections of Uterine Mucous Membrane immediately before and after Menstruation.

HUNTERIAN SOCIETY.

Chronic Dry Catarrh of the Middle Ear.—Value of the Microscopical Examination of Uterine Curettings.

AN ordinary meeting of this society was held at the London Institution on Nov. 24th, the President, Dr. G. E. HERMAN, being in the chair.

Dr. DUNDAS GRANT read a paper on the Diagnosis and Treatment of the Varieties of Chronic Dry Catarrh of the Middle Ear. He pointed out that there were essentially two different forms, one of the nature of an adhesive process resulting from a previous exudative catarrh and the other an

Digitized by Google

apparently primary adhesive process without evidence of any previous exudation. The former or exudative form arose by extension of the inflammation from the naso-pharynx through the Eustachian tubes; the latter or sclerotic was essentially a primary arthritis of the stapedio-vestibular articulation and had a tendency to involve labyrinthal structures. In the exudative form there was evidence of nasal disease and narrowing of the Eustachian tubes and the drum membrane was indrawn. In the sclerotic form the nose, Eustachian tubes, and membrane might be perfectly normal in appearance. In regard to diagnosis chronic dry catarrh of the middle ear had to be distinguished from an affection of the auditory nerve by the fact that the hearing by bone conduction was better than by air conduction and usually better than normal and that the loss of hearing power was greatest for deep tones. In nerve deafness bone conduction was less than air conduction and less than normal, while the loss of hearing was most marked as a rule for high-pitched tones. The diagnosis of chronic dry catarrh of the middle ear having been established the sclerotic form was to be distinguished from the exudative by its insidious onset, the very early occurrence of tinnitus aurium, the marked hereditary element, the absence of any distinct history of catarrh, the normal appearance of the nose and tympanic membrane, patency of the Eustachian tube on auscultation during inflation, and the improvement in the symptoms on inflation. The sclerotic form was more frequent in the female sex; it sometimes started at puberty and there was considerable evidence of its getting worse after the birth of children. There was possibly a bone change analogous to the osteophytic plates described by Moreau and Ducrest as occurring on the inner surface of the skull of women who died in child-bed. In other cases it was probably of an osteo-arthritic nature and occasionally syphilitic. In many, however, no cause could be made out and from the diminution of sensation in the membrane and the interior of the tympanum, as well as from the atrophy of nerves found in microscopical examination, it was possible that it was of the nature of a trophic neurosis. The prognosis was generally unfavourable and more especially in the sclerotic form. It was relatively favourable, &c., in proportion as the deafness depended upon narrowing of the Eustachian tubes, which was fairly amenable to treatment. Treatment in the exudative form was to be mainly directed towards the nose, naso-pharynx, and Eustachian tubes. The judicious use of Politzer's inflation, the Eustachian catheter, and above all the injections of liquid vaseline and the passage of solid or hollow bougies for the dilatation of the Eustachian tubes were of the utmost value. In the sclerotic form operations on the nose were on no account to be recommended. Injections and inflations did more harm than good. Massage of the tympanum and rarefaction of air in the external meatus was often the means of producing some improvement. Dr. Grant had considerable hopes of advantage from the adoption of general treatment appropriate to the dyscrasia, whether syphilitic or osteo-arthritic. He had seen benefit in the latter class of case from residence at Aix-les-Bains and in all cases a high altitude seemed advantageous.—Dr. KELSON asked if Dr. Grant believed that some of the tinnitus and vertigo might be relieved by application of chromic acid as recommended by Dr. Woakes and whether he would advise repeated inflations if the first proved unsatisfactory.—Dr. F. J. SMITH drew attention to the possible relationship between sclerosing otitis and the disease known as osteo-arthritis. He had not noted any particular frequency of deafness amongst the sufferers from the joint trouble.—Sir HUGH BEEVOR referred to a case of a young woman suffering from subacute rheumatoid arthritis who mentioned deafness occurring as part of the disease.—Dr. FORTESCUE FOX doubted if there was any frequent association of this affection with rheumatoid arthritis proper—at all events, in young females who were the most frequent sufferers from arthritis. On the other hand, chronic catarrh of the middle ear seemed to be relatively common in gout in which all other catarrhs, moist and dry, are met with. If a constitutional state of this kind underlies the catarrh one might hope that sufficiently early treatment would be effectual.—Dr. HERMAN asked as to the value of oxygen in a vaporiser and referred to the use of chromic acid by Dr. Woakes in the cases of hypertrophied mucous membrane of the nose. He spoke also of arsenic and its value.—Dr. DUNDAS GRANT replied.

Mr. TARGETT then read a paper on the Value of the Microscopical Examination of Uterine Curettings based on the results of the examination of more than 200 specimens during the past twelve months. The material consisted chiefly of fragments of tissue removed by operation from the uterus, but included with these were a few other specimens evacuated from the uterus or vagina the nature of which could only be determined by the microscope. A sketch of the routine method of investigation was given and the importance of certain details emphasised. The results of these 200 examinations were classified as follows: 1. Endometritis and endocervicitis represented 42 per cent. of the cases. In the large majority of these instances the clinical symptoms were suggestive of malignant disease and the examination was necessary to settle the diagnosis. 2. Malignant disease of all kinds constituted 32 per cent.; a few doubtful cases—probably malignant—had been included in the previous class with the exception of three (two being sarcomata and one deciduoma malignans). All these growths were carcinomata of the squamous or columnar-celled types. 3. In twenty-one instances—10 5 per cent.—the material consisted of degenerated placental tissue and as many of these cases had been suspected of malignant disease the value of a microscopical examination indicating the line of treatment was clearly demonstrated. 4. Sixteen—or 8 per cent.—of the specimens were classified as "membranes" and of these eight had the structure of a true decidual cast of pregnancy and four were menstrual in origin. Of the remainder two were fibrinous and two vaginal casts, the latter being composed entirely of epidermis shed from the surface of the vagina due to the use of too astringent injections. 5. On fourteen occasions—7 per cent.—nothing but blood clot was found which was partly due to want of proper care in collecting the curettings at the time of operation. In several instances the clot was partially decolourised having evidently been retained in the cavity of the uterus. The paper was illustrated by a series of microscopical sections.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.

Partial Suppression of Teeth in a Monkey.—Composite Odontome.

THE usual monthly meeting of this society was held at 40, Leicester-square on Dec. 6th, Mr. W. E. HARDING, President, being in the chair.

Mr. C. S. TOMES read a paper on Partial Suppression of Teeth in a very Hairy Monkey (*Colobus caudatus*). The specimen he referred to is in the Natural History Museum at South Kensington. The abnormality of the teeth at first sight suggested that the monkey under observation might represent a distinct species, but a close study of the teeth and the absolute identity of the skin with that of other specimens showed that it was an instance of reduction accidental in the individual, and as far as is known it is the only recorded example of great reduction in the teeth of a monkey. Mr. Tomes pointed out that in the human subject partial suppression of teeth has been found associated with redundant hair and also with paucity of hair, and hypertrophy of the teeth has been met with in at least one case of redundant hair—namely, in the case of Julia Pastrana, whose face was covered with hair—so that in the human subject all it was possible to state was that abnormality in hair is apt to be accompanied by abnormality in development of teeth. In the monkey under consideration the abnormality of the teeth was quite independent of any abnormality of hair, the animal having a similar amount to that usually seen in specimens of the same species. The reduction in the number of teeth consisted in the suppression of two pre-molars upper and lower on the right side and one pre-molar upper and lower on the left side. No incisors upper or lower were present in the jaws, but the appearance of the alveolus indicated that they may have been present although they must have been very small. The maxilla and mandible of the monkey were much reduced in size, but the remaining bones of the skull appeared to be of normal size in comparison with specimens of the same species.

Mr. W. R. BARRETT read the notes of an interesting case of Composite Odontome occurring in a Human Subject aged twenty-three years. The patient was a male and the odontome was situated in the mandible on the right side in the position of the second molar. The mass, which was rough

Digitized by Google

and nodulated, measured ⅛ in. in antero-posterior diameter, about ¾ in. from above downward and 1/16 in. across, and it weighed 102½ gr.

Mr. G. THOMSON referred to the question of Chloroform in Dentistry, the discussion being continued by Dr. HEWITT, Mr. BALDWIN, Mr. J. F. COLYER, Mr. TOMES, Mr. ROBBINS, and Mr. WOOD.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Acromegaly.—Symmetrical Nodes of the Radii in Women.—Stricture of the Œsophagus associated with Stricture of the Pylorus in the same patient.—Depressed Fracture of the Skull.—Ulcerative Purpura of the Legs.—Skiagrams and Pathological Specimens.

A MEETING of this society was held on Dec. 3rd, Dr. H. P. POTTER, President, being in the chair.

Dr. J. B. BALL showed a case of Acromegaly in a woman, aged fifty-one years. Menstruation ceased about twenty years ago and then gradually the facial features, hands, and feet began to enlarge. There was no retro-sternal dulness and the thyroid gland appeared to be of normal size. Headaches occurred but there were no ocular symptoms. The urine contained a little sugar. No specific treatment had been adopted.

Dr. SEYMOUR TAYLOR showed three cases of Symmetrical Nodes of the Radii in women. All the cases were of a syphilitic nature and two had other signs of syphilis. The symmetry was interesting and it was the lower sixth of the shaft of each radius which was affected. There had been much improvement under iodide of potassium and Dr. Taylor advocated the use of this drug in small doses at the commencement, instancing the fact that if a large dose be given to start with much iodide is excreted rapidly in the urine.—Mr. SWINFORD EDWARDS remarked that he had had very beneficial effects in nodes on the forehead from the use of iodide of sodium combined with carbonate of lithium.—Dr. CHAPMAN said he habitually gave the sodium salt.—Dr. MORGAN DOCKRELL thought that two of the cases were undoubtedly of acquired syphilis but that the third was probably of syphilis derived from the fœtus in utero. He advocated very large doses of the iodide.—Mr. J. R. LUNN, Dr. MANSELL MOULLIN, and Dr. A. WHITFIELD also discussed the cases and Dr. SEYMOUR TAYLOR replied.

Mr. C. B. KEETLEY showed one case of Stricture of the Œsophagus associated with Stricture of the Pylorus in the same patient and instanced another similar case. Both cases were the outcome of the swallowing of hydrochloric acid. In one case Mr. Keetley had performed Loreta's operation with marked success, but the other patient died before an operation could be undertaken. He alluded to the opinion he had formed that the stricture of the pylorus, which was organic, had really produced a spasmodic stricture of the œsophagus in much the same way as a stricture of the urethra may affect higher parts of the urinary tract. He insisted on early operative interference as soon as symptoms showed themselves.—Mr. J. R. LUNN alluded to cases which had been under his care. He was not in favour of Loreta's operation.—Dr. J. B. BALL also made some remarks.

Mr. MCADAM ECCLES showed a boy whom he had trephined for a compound Depressed Fracture of the Frontal Bone and alluded to another case of a simple depressed fracture also of the frontal bone. He advocated the replacement of bone in all cases where there was no septic infection of the same, but doubted the advisability of doing so if there was a suspicion of not being able to secure asepsis.—Mr. BRUCE CLARKE alluded to a case in which he had removed fouled bone and washed it and afterwards replaced it, primary union following.—Mr. KEETLEY preferred the use of a chisel and mallet to a trephine.

Dr. A. WHITFIELD showed a girl, aged eighteen years, with Ulcerative Purpura of the Legs.

Dr. F. H. LOW exhibited a large and interesting collection of Skiagrams chiefly illustrating the detection of foreign bodies in the tissues.

Mr. ERNEST CLARKE showed some beautifully prepared Ophthalmic Specimens of pseudo glioma, displaced lens, &c.

Dr. SEPTIMUS SUSDERLAND exhibited a Dermoid Cyst from an Ovary removed by laparotomy.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.

Complications of Scarlet Fever.—Leucocytosis.—Respiration, Normal and Abnormal.

A MEETING of this society was held at the Royal Kent Dispensary on Dec. 3rd, Mr. W. ARBUTHNOT LANE, the President, being in the chair.

Dr. SCHOLEFIELD read a paper on Some Complications of Scarlet Fever, in which he pointed out chiefly the characteristics of the so-called diphtheritic throat in the acute stage of scarlet fever. He showed (1) that it neither spreads to the trachea and larynx nor produces paralysis afterwards, nor does it infect other patients in the same wards who are convalescent from scarlet fever; and (2) that diphtheritic outbreaks among scarlet fever convalescents present quite different characters and are much more frequent where both diseases are admitted to the same hospitals, cross infection thus being rendered possible. He regarded the white patches as being purely streptococcal in origin. Rheumatism, albuminuria, and septic bronchitis were discussed, and nasal feeding was recommended for patients who swallow with difficulty and cough after the administration of fluids by the mouth.—The paper was discussed by the PRESIDENT, Dr. BOWEN WILLIAMS Dr. TAYLOR, Dr. PURVIS, and Dr. HERSCHELL.

Dr. HERSCHELL read a paper on Leucocytosis as an Aid to the Differential Diagnosis of Diseases of the Digestive Organs. He said that there was an increase in the number of white corpuscles in many conditions such as in inflammation, suppuration in any part of the body, absorption of toxins, and in most infective diseases except typhoid fever and tubercle. Besides materially assisting in the diagnosis between the chronic affections of the stomach, the counting of the leucocytes in the blood is of immense assistance in estimating the gravity of appendicitis. A small leucocytosis passing off after a few days showed that the affection was slight and limited in extent. A large leucocytosis maintained without change for a week showed that there was an extensive collection of pus walled in which had no tendency to be absorbed and that operation should take place without delay. A leucocytosis increasing from day to day showed that the disease was extending and that the patient was in danger and should undergo an operation at once. Cases of appendicitis in which a diagnosis could not be made have been reported in the medical journals, but if the blood had been examined there would have been no difficulty.

Mr. MAYO COLLIER read a paper on Respiration, Normal and Abnormal, in which he emphasised the need of making a thorough examination of the nose and throat in all respiratory affections.

KIDDERMINSTER MEDICAL SOCIETY.

Exhibition of Cases.

A MEETING of this society was held at the Kidderminster Infirmary on Nov. 26th, Mr. S. STRETTON, President, being in the chair.

Mr. LIONEL STRETTON showed:—1. A girl, aged twenty-five years, suffering from Chronic Rheumatism with Plastic Effusion around some of the Joints. She was first attacked with rheumatism about twelve months previously when she had an acute attack lasting about a fortnight. About six months after the attack the joints began to enlarge and had remained so since. The interphalangeal joints of both hands were swollen and slightly flexed, both wrists were swollen and stiff, and so also was the left elbow-joint. Around the first interphalangeal joints of the fingers there was a considerable amount of exudation giving them a peculiar appearance. Various forms of treatment had been tried without benefit. 2. A girl, aged four years, was admitted to hospital on Sept. 4th. She had fallen down with a glass in her hand causing a jagged wound in the palm and on examination it was found that the whole of the structures down to the metacarpal bones were divided. It was necessary to make an extensive dissection to divide the annular ligament and follow the tendons up the forearm in order to secure the proximal ends of those divided but after a tedious operation these and the nerves were all approximated. The wound healed without any trouble and there was very fair movement of the fingers. 3. A youth, aged seventeen years, who had had an

Digitized by Google

Undescended Testicle in the Left Inguinal Canal. In August last the canal was opened and the testicle was dissected out and pulled down to the scrotum where it was fixed with a suture. It remained in its position and showed no signs of atrophy; indeed it was considerably larger than the opposite one and could be moved about in the scrotum as in the normal condition.

Dr. EVANS showed a man upon whom he had performed Excision of the Elbow-joint for disease following an accident. The man who was a farm labourer found that he could do his work almost as well as before the accident.

Mr. W. H. MOORE showed a woman suffering from Ataxic Symptoms of an Obscure Nature which he thought might be due to a small tumour in the cerebellum.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Forceps and Forceps Mortality.—Vaginal Section versus Abdominal Section.—Phenacetin.

A MEETING of this society was held in the Medical School, Sheffield, on Nov. 19th, Dr. BRIGGS, President, being in the chair.

Dr. MACFIE CAMPBELL (Liverpool) read a paper on Forceps and Forceps Mortality in which he maintained that delivery by means of instruments was not more common among the poor than among the rich, that the amount of disease or injury was not increased by their use, and that the risk to mother and child was not increased. The use of forceps in general practice was largely a question of whether chloroform was employed or not, for if it was then forceps would be more recognised in upper-class practice. By that he meant the low operation, and while his own percentage of forceps deliveries was 29 per cent. four-fifths of these were low operations. As for disease and injury he thought the gynæcologist was in the present day employed more than formerly because he could do more, not because there was more to be done. That laceration of the perineum occurred in 85 per cent. of cases of forceps delivery according to Münchmeyer he doubted from his own experience in which he sutured every case, even the slightest. The diminution of cases of vesico-vaginal fistula was noted by more than one observer, among whom might be quoted Dr. Playfair. Of 107 primiparous forceps cases Dr. Campbell had lost one mother, a craniotomy case, and four children three of whom were twins; while of 230 forceps cases (taken altogether) he lost three mothers (two craniotomies and an eclampsia) and nine children.

Dr. WALTER (Manchester) made some remarks on the relative advantages of Vaginal Section *versus* Abdominal Section. He also exhibited a Dermoid Ovarian Cyst removed by Vaginal Section and a Piece of Glass Drainage-tube removed by Vaginal Section on the fourth day after Ovariotomy.

Dr. LLOYD ROBERTS (Manchester) recommended Phenacetin as an alternative to opium for the relief of pain in cancer of the uterus, rectum, and mammary gland. It did not produce gastric disturbance or constipation. In severe cases the amount required was 30 gr. in twenty-four hours given dry and washed down with a little cold water.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.—Retained Placenta after Abortion.

A MEETING of this society was held on Nov. 25th, the President, Dr. SINCLAIR WHITE, being in the chair.

Dr. COCKING showed a boy, aged six years, suffering from Cerebral Tumour. The history of the illness was as follows: In February, 1897, there was severe headache accompanied by vomiting for six weeks, in April weakness of the left arm (gradual onset), in June gradual loss of sight, and in August gradual weakness of the left leg. The patient's condition when shown at this meeting was as follows. There were commencing optic atrophy (post papillitic), left hemiplegia the arm, leg, face, and tongue (slightly) being affected; the deep reflexes were exaggerated and the superficial were diminished on the left side; there was no loss of sensation, no headache or vomiting; the patient had never had convulsions; there was no albuminuria, tuberculosis, syphilis, rheumatic fever, ear disease or injury. There was nothing in his family history.

Dr. BURGESS showed: (1) a mother and child and two sisters, all suffering from Congenital Heart Disease; (2) a case of Xanthoma Multiplex with, among other features, multiple periosteal swellings along the edges of the ulnæ and tibiæ; and (3) a man who had for thirteen years with remissions and exacerbations exhibited frequent and varied Movements of the Face, Head, and Limbs. The movements though apparently voluntary were denied to be so, and as far as could be ascertained there was no motive for making them.

Dr. PORTER showed a specimen of a Heart with well-marked Stenosis of the Pulmonary Valve. The patient was twenty-nine years of age and the affection was congenital. He had, however, continued work up to a few weeks before death which occurred from pulmonary tuberculosis. He had no cyanosis and no clubbing of the fingers, and until a few months before death he had only complained of shortness of breath. The physical signs consisted of the single systolic bruit and thrill over the pulmonary artery conducted towards the left clavicle.

Mr. RICHARD FAVELL read notes of a case of Retained Placenta after Abortion and made remarks on the treatment of such cases. Mr. Favell also showed specimens of Ovarian Dermoids removed by operation.

Mr. ARCHIBALD YOUNG showed a patient who had been recently successfully operated on by Dr. Sinclair White for Abscess of the Lung.

Mr. ARCHIBALD CUFF read notes and showed specimens of (1) a case of Scirrhus of the Male Breast, and (2) a case of rapidly growing Soft Cancer commencing simultaneously in both breasts. Mr. Cuff also exhibited a series of microscopical slides illustrating the chief diseases of the breast.

The PRESIDENT, Dr. HARGREAVES, Dr. SWEETEN, Mr. LOCKWOOD, Dr. MARTIN, Dr. THOMSON (Retford), Mr. PYE-SMITH, Mr. ATKIN, Mr. BENSON, and Dr. BURGESS made remarks on the cases and specimens.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

Some Points of Living Interest to the Teacher of Gynæcology and Obstetrics.—Ruptured Tubal Pregnancy.—Exhibition of Specimens.

A MEETING of this section was held on Nov. 26th, Dr. F. W. KIDD, the President, being in the chair.

The PRESIDENT having thanked the section for electing him to the presidential chair for the ensuing two years delivered an introductory address on Some Points of Living Interest to the Teacher of Gynæcology and Obstetrics. He dealt with the position of the "lady student" as regards her attendance on mixed classes of instruction, her position afterwards as a qualified practitioner with regard to the specialities of gynæcology and obstetrics, and her position as a unit of the profession to which she belongs. He drew attention to the fact that the difficulties in her way were: (1) custom; (2) men are already in possession; (3) physique; and (4) the suspicion or rather want of confidence with which one woman usually regards another woman. He dealt with the question of the improvement in nursing, recognising that it was a boon to both patient and practitioner but not an unmixed blessing and he drew a fine distinction between "lady nurses" and "nurse ladies." He drew attention to the objections to a Midwives Registration Act and inferred that there would not be the same amount of interest taken in it in England that there undoubtedly is if the poor were provided with as good nurses as there are in Ireland. The advantages possessed by students who study gynæcology and obstetrics in Dublin were pointed out, especially the facilities afforded for practical work, and attention was drawn to the fact that the Conjoint Board of the Royal Colleges of Physicians and Surgeons, London, while refusing to acknowledge a course of practical work for three months taken out at a midwifery hospital such as the Rotunda or Coombe Hospital, nevertheless

Digitized by Google

accepted as evidence of practical midwifery a certificate stating that the student had "attended" not less than twenty labours and this need only be signed by one qualified practitioner. The Irish licensing corporations — Dublin University, the Royal University, and the Conjoint Royal Colleges of Physicians and Surgeons—require a six months' attendance on practical midwifery in a lying-in institution and a certificate of having attended at least thirty labours.—Dr. MORR MADDEN proposed that the President's admirable address should be printed in the Transactions of the Academy.

Dr. ALFRED SMITH read notes on a case of Ruptured Tubal Pregnancy which occurred in a young married woman, aged twenty-nine and a half years. She was five years married and had three full-term children. Cœliotomy was performed and there was removed a Fallopian tube of the left side which showed a rent through its inferior border at the junction of the ampulla with the isthmus. There was also to be seen a large circular opening sufficient to admit the tip of the index finger in the posterior layer of the broad ligament quite close to the rupture and leading to it. A tuft of chorionic villi and also a fœtus were enveloped in its amniotic sac. The latter was about half an inch long and was approximately the growth of between the eighth and tenth week of gestation. The points of interest seemed to be: (1) the occurrence of a tubal pregnancy in a patient so prolific; (2) the history of a secondary rupture, for pain first occurred on May 17th last, then there was a period of quiescence followed by a return of pain on May 22nd, and the pathological specimen shows evidence of a primary rupture between the layers of the broad ligament and a secondary one into the peritoneal cavity; (3) the absence of any hæmorrhage per vaginam; and (4) the fact that the patient is again pregnant since August so soon after such a serious operation.

Dr. JELLETT showed for Dr. PUREFOY a case of Ruptured Tubal Pregnancy. The patient was admitted to the Rotunda Hospital on Aug. 12th, 1897. Her last pregnancy was March 12th, 1897. She stated that she was unwell seven weeks after delivery, then had amenorrhœa for two months, followed by hæmorrhage and bearing-down pains and after this had seen nothing since July. Upon admission she complained of pain in the back and iliac regions and of dysuria. An irregular tumour filled Douglas's pouch; the uterus was not considered to be enlarged. Her general condition was bad and operation was deferred until Aug. 31st. At the operation the uterus was found to be enlarged to about three and a half months' pregnancy; the tumour in the posterior *cul-de-sac* was adherent and on removal proved to be a tube distended with blood; as it was thought possible the enlargement of the uterus might be myomatous the other tube and ovary were removed. The patient left the hospital on Sept. 28th and the uterus was then the size of a five months' pregnancy; she was subsequently delivered of a premature child on Oct. 22nd. On microscopic examination the tube was found to contain the remains of a fœtus and placental tissue.

Fifty gynæcological specimens were exhibited by, or for, Dr. HENRY JELLETT, Dr. W. G. SMYLY, Mr. T. HENRY WILSON, Dr. E. HASTINGS TWEEDY, Dr. ALFRED J. SMITH, and Dr. R. D. PUREFOY.

WATER-SUPPLY OF CHARD, SOMERSET.—At the meeting of the Chard Town Council held last week the Water Committee presented a report in connexion with the proposal of the council to obtain a water-supply by means of gravitation from Combe St. Nicholas.

UNIVERSITY OF CAMBRIDGE.—The new Professor Chinese is Dr. H. Allen Giles, of Aberdeen.—Mr. W. H. Rivers, M.D. Lond., of St. John's College, has been appointed a University Lecturer in Physiological and Experimental Psychology.—Mr. W. L. H. Duckworth, Fellow of Jesus College, has been recognised by the Special Board for Biology as a Lecturer in Anthropology.—The Walsingham medals given by the High Steward for the encouragement of physiological and biological research have been awarded to Mr. V. H. Blackman, of St. John's College, and Mr. W. Morley Fletcher, Fellow of Trinity College. The University has appointed Dr. D. MacAlister and Dr. Anningson as its delegates to the International Congress of Hygiene and Demography to be held at Madrid in April, 1898.

Reviews and Notices of Books.

A System of Practical Medicine. By American Authors. Edited by ALFRED LEE LOOMIS, M.D., LL.D., and WILLIAM GILMAN THOMPSON, M.D. Vol. I., Infectious Diseases. London: Henry Kimpton. 1897. Price 25s. net.

ALTHOUGH opinions may differ as to the immediate necessity of adding to the number of works on systematic medicine there can only be one sentiment as to the character of this the latest addition to the library of the practitioner. In the style and substance of its contributions as well as in the handsome manner in which the work has been produced it leaves nothing to be desired. It is to be completed in four volumes, but since its initiation death has removed one of its editors, the accomplished Dr. Loomis, as well as one of the contributors to the present volume, Dr. John M. Byron, formerly director of the bacteriological department of the New York University Medical Department. The multiplication of works of this class, built up by the labours of many writers, must be taken as an index of the vast extension of medical science in every department. It has grown to such proportions as to be beyond the capacity of a single author to do it adequate justice, and if thereby the reader loses the unity of thought that must pervade the work of one hand he gains the more thorough and detailed study of each of the subjects which proceeds from their being assigned to different pens.

The present volume is devoted to Infectious Diseases. It opens with an elaborate study of Malarial Fevers, the interest of which at the present time mainly centres in the hæmatozoal parasites, the discovery of which is due to Laveran. Dr. W. H. Welch, of Baltimore, tells all that can be told upon this part of the subject, and that, too, in a manner which carries conviction with it. When discussing the question of pathology he ably shows how much that was obscure in the clinical history of these affections has been made plain from the facts ascertained about the life-history of the malarial organisms; and although doubtless much remains to be discovered to bring these facts into harmony with other etiological data there is good reason to believe that they will some day be obtained. The clinical, pathological, and therapeutic aspects of malarial fever are dealt with by Dr. W. S. Thayer, of Baltimore, who contrives to differentiate the various types and forms of these fevers in a lucid manner. To those whose medical experiences are gleaned in districts infected by these diseases such a differentiation must be welcome, whilst even to the academic student the gain in clearness of conception of their nature that accrues thereby can be best appreciated by comparing the present exposition of the subject with that to be found in text-books of twenty or even ten years ago. It is gratifying to find it affirmed that "typho-malarial fever as a distinct entity does not exist," for the introduction of that term has been one of the most misleading and puzzling in the nomenclature of disease. A case of typhoid fever may be complicated with malaria, or the converse, but no doubt Dr. Thayer is correct when he says (p. 134):—

"There is little doubt that the enormous majority of cases referred to to-day as 'typho-malarial' fever in this country and elsewhere are cases of typhoid fever, pure and simple. Too much stress cannot be laid upon this point, for the groundless assumption that there exists in this country a fever due to the combined action of typhoid and malarial poison, pursuing a fairly characteristic course and calling, from its malarial nature, for the continued use of quinine, has exercised in the past, and is exercising to-day, an extremely injurious influence upon the medical practice of this country.'

Digitized by Google

Similarly the writer of the article on Typhoid Fever says (p. 198) that this term—i.e., "typho-malarial"—is "an unfortunate one and has given rise to no little confusion concerning the nosological conditions of the various forms of disease to which it has been applied." Dr. J. C. Wilson, of Philadelphia, contributes the article on Enteric or Typhoid Fever, and it is a most able and accurate description of a disease which is known the world over. There are few points to criticise in this article, but we should have liked somewhat more attention paid to the subject of ulcerative colitis in relation to typhoid fever, and especially with regard to the features of an attack in which such involvement of the large bowel in the morbid process is marked. Our impression is that nearly all such cases are fatal, the diarrhœa being most continued and exhausting. It was hardly to be expected that the "agglutination test" should have received mention, for works of this class take some time to compile, and the reaction is one of comparative novelty. Dr. Wilson is a strenuous advocate of the cold bath treatment (by the way for "Curry" should be read "Currie," the pioneer in this line), his own experience being highly favourable to its systematic use, whereby it is claimed that the fatality is lowered to 7 or 8 per cent. Dr. G. M. Sternberg writes on Yellow Fever, than whom few are better entitled to speak with authority, but his declaration that the "yellow fever germ" has yet to be demonstrated was doubtless written prior to the recent researches of Dr. Sanarelli. The late Dr. Byron's article on Cholera is noticeable for his entire adhesion to the causative agency of Koch's comma bacillus of which a full description is given. Dr. Hamilton West, of Texas, deals with the somewhat involved subject of Dysentery in an able manner, differentiating pathologically and clinically the forms of (1) acute catarrhal dysentery; (2) diphtheritic dysentery; and (3) amœbic dysentery. Some excellent plates of the amœba are given. Influenza is described by Dr. J. C. Wilson, and Epidemic Cerebro-spinal Meningitis by Dr. T. S. Latimer, of Baltimore. Dr. W. M. Welch, of Philadelphia, contributes an excellent account of Small-pox and Varioloid, comprising under the latter head all forms of modified small-pox, which he correctly says may present all types of eruption, but which are sharply demarcated from the true disease by the manner in which they abort in their course and in which secondary fever is lacking. Dr. Welch also writes on Varicella, his remarks on the differential diagnosis from variola being especially to the point. The difficulty, which may be a very real one, is enhanced when severe varicella occurs in the adult, for this disease is not, as some say, limited to childhood. The same subject is dealt with in almost the same manner by Dr. Lenhartz in the last number of the Hamburg Hospital Reports. Of its practical importance it is needless to speak. In the article on Vaccinia Dr. Welch writes with judgment, but we must take exception to the very highly-coloured drawing supposed to represent the mature vaccinal pustule and areola.

Dr. W. H. Park, of New York, in the article on Diphtheria enters very fully into the bacteriology of the subject, and does good service by his attempt to clearly define the nature and relationships of "pseudo-diphtheria." This is a subject which certainly requires most thorough investigation and it is one which has entirely arisen out of bacteriological studies. Upon the value of antitoxin Dr. Park speaks with no uncertain sound. He devotes several pages to its discussion and furnishes numerous statistics, the most instructive being reports on 24,768 cases furnished to him by Dr. Girade. Surely the accumulated testimony is all-sufficient to establish the efficacy of this remedy, of which Dr. Park says (p. 707):—

"Diphtheria antitoxin has a marked curative effect in diphtheria. The results are very striking when the injections are used early in the disease and when the diphtheria is uncomplicated with pneumonia or sepsis. In well-developed cases and in those having complications its benefit is less marked. In cases already profoundly under the influence of the diphtheria toxin and in a dying condition it is useless."

Professor W. Osler writes upon Tuberculosis. It is needless to say that the subject is treated in a thoroughly scientific as well as practical manner, and as it comprises all manifestations of the infection, including pulmonary phthisis, his contribution forms by itself a monograph of no mean order. Amongst other articles are those on Syphilis, by Dr. W. F. Robinson, on Leprosy, by Dr. J. Dyer, and on Tetanus, by Dr. James Stewart. The work is, indeed, one of a high class, and will be all the more welcome as the selection of writers has evidently been made with great judiciousness, so that their contributions represent fully the high position which American medicine may well claim to have attained.

LIBRARY TABLE.

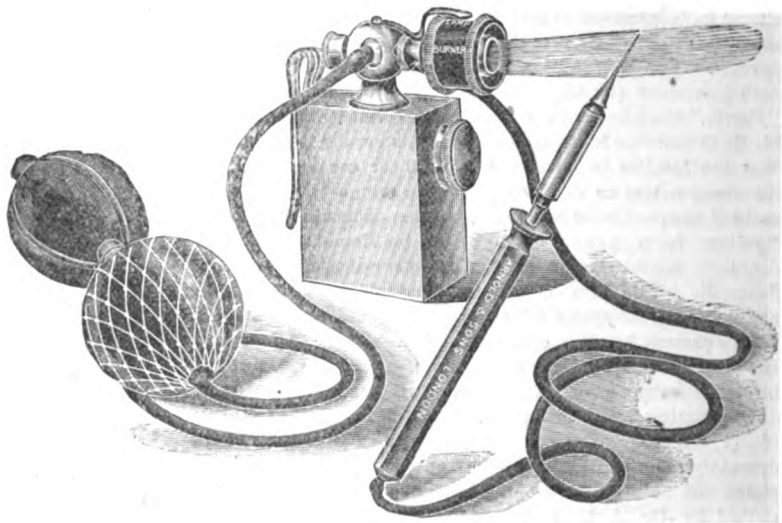
Chirurgische Operationslehre. (*A Manual of Surgical Operations.*) Von Dr. TH. KOCHER, Professor an der Universität und Director der Chirurgischen Klinik der Universität Bern. Mit 213 teilweise farbigen Holzschnitten im Texte. Dritte vielfach umgearbeitete Auflage. Jena: Verlag von Gustav Fischer. Pp. 412. 1897. Price 11 Marks.—We have recently reviewed the English translation of the second German edition of this work and though various slight alterations have been made in this edition yet they are not such as to alter the character of the book. In estimating the value of this treatise it must be remembered that it was never intended to give an account of all the varieties of surgical operations which ever have been, or even now are, performed. Professor Kocher has limited the scope of the work to the inclusion of those operations which he himself is in the habit of using or which are generally recognised as of value, but even with this restriction the volume contains all that is really required. Its abundant and excellent diagrams and the clear descriptions of the surgical procedures combine to make it one of the most valuable of the many treatises on operative surgery.

The American Year-book of Medicine and Surgery. Collected and Arranged with Critical Editorial Comments under the general editorial charge of GEORGE M. GOULD, M.D. Profusely illustrated. London: The Rebman Publishing Company. Pp. 257. 1897. Price 38*s*.—We had occasion in reviewing the first appearance of this work last year to speak of it in terms of almost unqualified approval and the present volume is in no way behind its predecessor. The only alteration in the editorial staff has been the accession of Dr. Dühring, who is responsible for the department of Dermatology. A very valuable feature of this year's volume is a brief summary of the results of the whole year's work which precedes each article. The editorial comments, which were one of the most noteworthy characteristics of the volume for 1896, are again of the utmost value to all those who have not the time or opportunity to investigate the claims of every new departure which is made in medicine or surgery. The names which are attached to the several departments are in themselves a guarantee of the excellence and exactness of the abstracts. The work is one which should be in the possession of every medical man who wishes to know all that has been done during the past year in any department of the medica sciences. We shall look forward to its reappearance year by year.

Cutaneous Medicine. By LOUIS A. DÜHRING, M.D. Part 2. London: J. B. Lippincott Company. Price 12*s*. 6*d*.—A general classification of diseases of the skin occupies the

Digitized by Google

first few pages of this volume. There has always been a difficulty in obtaining any scientific classification in this branch of medicine and many different methods have been tried. Until the knowledge of skin diseases is complete enough to make a classification on strictly scientific lines the great object is to obtain the one which will be most serviceable in practice, and the author thinks that the one which he adopts will be found to fulfil all requirements. He classifies the diseases under the following heads: Anæmias, Hyperæmias, Inflammations, Hæmorrhages, Hypertrophies, Atrophies, Neoplasmata, Anomalies of Gland Secretion, and Neuroses. As may be imagined, the group of inflammations is the largest and it is rather surprising to find the parasites in this group, for although their effects are doubtless of an inflammatory nature they surely deserve a separate group to themselves. On turning to the body of the book it will be found that the subject of eczema claims the largest share and this disease and its many variations are very fully described. The illustrations are very numerous and admirably executed, but unfortunately very little can be learnt from pictures of skin diseases which are not coloured, for so many of the finer differences depend upon colouration that in uncoloured plates one kind of ulceration must necessarily look much like another. The plates of pathological sections, however, do not need colour and they convey an excellent idea of the morbid anatomy of the different diseases.



The *Journal de Clinique et de Thérapeutique Infantiles* of Nov. 18th contains a careful study of Infantile Glaucoma by Dr. Rochon-Duvigneaud. As regards causation the writer makes no definite addition to our knowledge of the disease. He notes, however, its prevalence in infants of weak neurotic type as well as its extremely early, even intra-uterine, origin which is the frequent occasion of its being overlooked. He draws attention to the fact that the glaucomatous globe in the infant presents, in addition to the usual symptoms, a peculiarity, unknown in the adult—i.e., that it slowly becomes dilated and actually increased in size. This enlargement is a natural consequence of tension on tissues which are still distensible. The point is of some practical importance, for Dr. Rochon-Duvigneaud reminds us that eyes which have undergone such dilatation are unsuitable for iridectomy and are readily liable to such accidents as hæmorrhage, luxation of the lens, escape of vitreous, and detachment of the retina. Prior to enlargement iridectomy as in the adult is of the greatest value (von Muralt, Horner). After this condition is established he strongly advises sclerotomy repeated as often as needful and quotes Arnold[1] in support of the excellent results obtained by this method. He has not found eserine or pilocarpine as useful as in the adult in arresting the progress of infantile glaucoma and he relies upon them chiefly as aids to operative measures which they facilitate by contracting the pupil and reducing tension. The differential diagnosis between glaucoma and exophthalmos, myopia, tumours of the retina and choroid, and the rare disease known as keratoglobe, in which the corneal curve is actually increased, is also discussed with due care in this interesting paper.

New Inventions.

NEW PORTABLE CAUTERY.

THE diagram shown below represents a modified form of Paquelin's cautery made for Messrs. Arnold and Sons without any glass parts (which so easily get out of order and break). This new form is composed entirely of nickel-plated metal (except the bellows) and does away with the necessity for a spirit lamp which has always been a source of danger. The metal reservoir is half filled with benzine and to heat the cautery the regulator has simply to be turned to the word "Lamp" and the lamp then lighted when a powerful

flame is produced and the cautery is heated in less time than by the ordinary Paquelin's cautery. When this is done the regulator is turned to the word "Burner" and the operation can at once be commenced, retaining a perfect burning surface as long as required. When finished by turning the regulator to the word "Closed" the action is immediately suspended. The cautery is not only simple and quicker in its action but it has the great advantage of being extremely portable; the case containing the instrument only measures six inches long, four inches wide, and one and a half inches deep, and the whole apparatus is sold at a moderate price.

CYCLE HANDLE-BAR TABLOID MEDICINE CASE.

THIS is a handy little case for carrying either the things with which the bag is fitted or any other instruments or drugs that may be preferred or that suit any particular emergency. It is made of waterproof leather, measures 8¼ in. by 4¼ in. by 2⅜ in. (outside measurements), is fitted with loops for bottles and small instruments, can be easily and quickly attached to the handle-bar, and is so constructed that while still strapped to the handle-bar the case may be opened and anything required may be taken out. The case submitted to us was fitted with scissors, knife, clinical thermometer, spring forceps, caustic-holder, eye-dropper, adhesive tape and court plaister, two bandages (3 in.), lint, box of safety pins, a tube of hazeline cream, and nine bottles for drugs—some in liquid and others in tabloid form. It seems impossible to construct a very portable and small case to contain everything that may be required for all emergencies, and some to whom a little extra weight is of no consideration might prefer a larger case; but, as the above list of its contents shows, this case, which weighs when empty 10 oz., is sufficiently capacious to contain a variety of instruments, &c. The price of the fitted bag is £1 13s. and the makers are Messrs. Burroughs, Wellcome, and Co.

THE LANCET.

LONDON: SATURDAY, DECEMBER 11, 1897.

THE General Council of Medical Education and Registration came to the end of its sixty-third session on Tuesday, Nov. 30th, having sat for seven days. It may be doubted whether the Council ever did in so few days so much work. Opinions differ as to the capacity of the Council for the work contemplated by the Legislature in creating it—which work may shortly be defined as the supervision of medical education for the purposes of pass examinations and the duty of medical registration with a view to keeping the Medical Register accurate and purging it of names which discredit the profession. But the severest critics of the Council must allow that in seven days it has dealt with an enormous number of subjects and has contrived to look at them from many sides and from many points of view. There has been little waste of time; indeed, on one or two subjects more time might well have been spent. The conclusions reached with regard to some of the questions may not be universally approved, but we mistake if it will not generally be conceded that for so large a body representing such a variety of interests and dealing with such a variety of subjects the work has been done in a fairly business-like fashion. We have already dwelt upon what may be regarded as the *magnum opus* of the week's proceedings—the dismissal of the unqualified assistant from sharing the responsible work of the profession. If anything were wanted to justify the act of the Council it will be found in the penal cases tried during the session, showing the plights into which medical men are brought by the employment of unqualified assistants and the discreditable mockery of medical practice which such employment involves. It is impossible not to feel a certain amount of pity for the individuals who form the class which is now extinguished, but it must be remembered that unqualified assistants have had long notice of their coming disestablishment and that the General Medical Council has acted by no means precipitately. We refer to other aspects of the question in another column.

A feature of the session just concluded has been the discussion of points of law arising out of the Medical Acts themselves, out of the decisions of the courts, or finally out of the by-laws of the Council. Many of the most important and interesting of these discussions have involved personal and delicate questions and have almost necessarily had to be discussed *in camerâ*. All such discussions are apt to be complicated by the inevitable collision of strictly legal interpretations with that professional judgment which is expected from the Council not as a court of law but as a domestic tribunal for the judgment of professional conduct. There is a whole host of such questions on which the judges themselves are not agreed or have given no certain sound. It must be the endeavour of the Council to work steadily and quietly at the process of eliciting legal decisions on vital points. The minutes show that a noticeable step in this direction has been taken by the Council in instructing its law officers to proceed with various prosecutions which will test the efficiency of the present law in restraining the action of persons with "bogus" or with foreign qualifications. Persons removed from the Medical Register and therefore presumably legally unqualified will also be prosecuted if they continue to use professional titles and to practise as if their registration and their professional honour were both intact. In short before another session of the Council comes round many things will have happened and among them doubtless several prosecutions which will throw light on the sufficiency of the present Medical Acts. If the cases for the prosecution should show weakness against fully proven abuses it will be the duty of the Council to lose no time in asking Parliament for more effective clauses to guard the public and the profession whose interests are identical. A large portion of the time of the Council has been occupied by the discussion of questions arising out of the inspection of examinations under the Dentists Acts and of the right of the General Medical Council—or rather its Executive Committee—to register persons, including foreigners, under the latter part of the Thirty-seventh Clause of the Dentists Acts by special order. Time might be saved by due notice to the dental profession of proposals in which it has a deep and natural interest.

Another important subject on which the Council has taken a step forward is that of Preliminary Education. It is a happy proof of the addition to the strength of the Council that two of its new members made interesting and important speeches on this subject. Sir CHRISTOPHER NIXON, the new representative of the Royal University of Ireland, and Mr. VICTOR HORSLEY, recently elected as a Direct Representative, respectively proposed and seconded a motion that the Education Committee should be called on to report on a scheme under which a preliminary examination might be instituted "for medical students of a standard uniform throughout the United Kingdom—such examination to be wholly conducted by the General Medical Council." The idea is a captivating one but scarcely practicable at present. The General Medical Council has enough on its hands to secure fair uniformity and efficiency in the strictly professional examinations of the country, with regard to which by its very catholic constitution it may be supposed to have ample materials and knowledge for judgment. As an authority on general education it has no standing and it can scarcely pretend to compete with the recognised educational bodies of the country upon which it has always sought to throw the responsibility of preliminary examination. The Council has done well to provide for a decided rise in the standard of general education. If it has not gone far enough it has taken a very sensible step in the right direction.

IT is now more than a quarter of a century since THE LANCET Commission on Nursing in Workhouses first aroused public opinion as to the shocking state of things which existed in these institutions. Consequently on this Miss

Digitized by Google

TWINING with Lady LOTHIAN and Lady MONTAGU of BEAULIEU formed, with other ladies and gentlemen, an association the objects of which were to improve the state of nursing in workhouses by promoting the employment of paid and efficiently trained nurses. In the eighteen years during which this association has been in existence its members have trained at their own expense, and with money raised by public subscription, nearly 400 nurses, and have been the means of nearly as many women trained elsewhere taking posts in workhouses and infirmaries.

A report of the general meeting of this association will be found in another column, and it is with great regret we find that it is about to cease the good work upon which it has been engaged. In view of the new Workhouse Nursing Order recently issued by the Local Government Board, to which we have already called attention, we cannot help thinking it is a pity that the association should have chosen this moment for bringing its work to a close. The Order itself is the outcome of the efforts of the association and although, as we have pointed out, the new Order accomplishes a very small part of a much-needed reform, nevertheless it is a considerable step towards the much-to-be-desired end that pauper nursing should be completely abolished. It is a matter of great regret that this Order uses the vague term "experience" instead of "training," as Miss TWINING pointed out at the meeting. We are also aware that the difficulties attaching to the position of a workhouse nurse are so great that it is hard to find suitable women to undertake the work, when there are so many attractions elsewhere, particularly in the way of private nursing. There is no doubt that the time has now come when the central authority should take up this matter of organising a training school for workhouse nurses and for introducing reforms as regards increased salaries, pensions, regulations for duty, and the like, so as to constitute a separate and more attractive service of its own on the same lines as has recently been done in the army and navy. At the same time, the very fact that the new Order is faulty and that matters are in such an unsettled condition makes it desirable that a committee of experienced ladies and gentlemen, such as that of the Workhouse Association, should not withdraw altogether from the arena. It was abundantly evident from what took place at the meeting that there are many guardians who greatly appreciate and value the aid and advice of the association, and the nurses supplied to them by it. Very probably after this they would be willing to subscribe, as they ought to do, far more liberally than heretofore. We cannot help thinking that if the guardians be left entirely to their own devices in the rendering of this Order it will result in a retrograde movement and the employment by them, under the cover of what are called "experienced" women, of women of a very inferior stamp, many of whom could not pretend to any kind of training, and that the tone of the service of nurses in workhouses will inevitably deteriorate.

We fully realise the difficulties with which the association has to deal, and has had to deal, for they are not new ones; it is simply that they have been recently growing more acute. If we could agree with Miss TWINING in her hopes that the cessation of the Workhouse Association would result, in the near future, in the creation of a State department—and undoubtedly such a creation would be of great value even if not a matter of necessity—then undoubtedly we might regard it as a correct step. But we cannot help thinking that the creation of such a department is still far off; and in the meantime the guardians, being compelled to employ nurses and not being able to obtain trained ones, will—indeed, they must—employ those who possess only what is called "experience"—a lax term which we fear will become still wider in its application in the absence of the Workhouse Infirmary Nursing Association.

IT was in a way fair that a period of transition should elapse between the restriction of the use of the unqualified assistant and his extinction. He had long been a sort of recognised agent in medical practice and in some instances he only escaped obtaining a legal position in the profession by an accident of date, for the Medical Act of 1858 contains a clause for the registration of persons without qualification who were in practice before 1815. For a quarter of a century after the passing of the Act medical practitioners went on employing unqualified assistants without any intimation from the General Medical Council that they were doing anything wrong or unlawful, and undoubtedly the fact that the possession of the diploma had only recently become a necessity conduced to some obtuseness on the point. Still, the passing of the Act was a hint to the unqualified that they were in an unsatisfactory position and one which could not be permanently defended. It was also a hint to practitioners that the use of unqualified persons might easily assume a fraudulent appearance and place their employers in a false position. Unfortunately this was not recognised even by the Council itself, for it was not till the year 1883 that it awoke to the fact that it had responsibilities as the chief ethical authority over medical men in the matter of the wide employment of unqualified assistants. About this time a case where such employment had had serious results was brought to the notice of the Home Secretary who referred it to the General Medical Council. The Council responded by giving a broad, if somewhat vague, notice to the profession that a medical man employing an unqualified assistant, save under his immediate supervision, to do duties only proper to be done by a registered practitioner was exposing himself to the risk of being considered guilty of infamous conduct in a professional respect and consequently of erasure from the Register. We tried at the time to give practitioners a rough idea of what we thought the Council meant and the limits within which it permitted the use of unqualified assistants. Our note on the subject in our advertising columns was constructed after due consideration of cases tried by the Council and after conference with some of its more authoritative members.

Two things have been notorious for some time—firstly, that the action of the Council was not efficient—i.e., either it did not reach practitioners or was not understood; secondly, that the vagueness of its notice enabled the Council to vary its judgments so much that practitioners

Digitized by Google

lost respect for its edicts and have continued to employ unqualified assistants to this day on an enormous scale. The Council accordingly has proclaimed its intentions in more uncompromising terms. We must emphatically decline to say exactly what is meant by the recent notice (for the text of which we refer our readers to our advertisement columns, p. 93), nor can we in answer to numerous correspondents define the cases in which unqualified persons not being *bonâ-fide* pupils may be employed by practitioners. We shall not even venture to decide the point raised in the *Times* of the 6th inst. where an unqualified assistant claims a right to a fair notice of the termination of his engagement, though we must venture to doubt whether the Council ever meant to carry its point so violently as the denial of this claim would imply. The Council still seems to recognise in addition to the use of medica lstudents as *bonâ-fide* pupils "the *legitimate* employment of dressers, midwives, dispensers, and surgery attendants under the immediate personal supervision of registered medical practitioners." Though the Council would seem to have decided to recognise no assistant but a well-advanced student, not receiving money from his principal but paying his principal for training and instruction, it still leaves a goodly army of officials to be "legitimately" employed, and under one title or another it seems not improbable that our old friend "the unqualified assistant" may show himself to be not extinguished. We shall now hear much doubtless of the dispensing assistant and he is a very important person. It is notorious that the great majority of medical students not sons of actual practitioners are not *au fait* at dispensing and only those who live in the transcendental regions of the profession will deny the importance of ready and efficient dispensing in the general practice of the country. Fine questions will arise over the acts of this official if they seem in any emergency to exceed the modest but important *rôle* assigned to him. Altogether, unless the Council sees its way to be more specific there is little doubt the language of its new regulations will furnish material for an ever-increasing number of charges against medical practitioners which may make still heavier demands on its time and its financial reserves than even the cases with which we have been hitherto familiar.

It is only fair to admit that if the profession is agreed as to the severity of the new regulations it is almost unanimous with regard to their justice. It is monstrous to insist on severe examinations and a long curriculum for medical students if those who evade such labours are allowed to act as if they had undergone them. The public itself would have just reason to distrust the General Medical Council if it allowed a large amount of medical practice to be done by unqualified persons "covered" by those who enjoy the privileges of registration. But all this only makes it the more imperative that the Council should be explicit and clear. The necessity for such clearness is the greater as the new regulations affect a much larger number of persons than did the old ones, for the number of practitioners having unqualified assistants in their service whom they have employed in the manner hitherto deemed legitimate is much larger, we are glad to believe, than the number of practitioners who deliberately practise the trick of coveria

Annotations.

"Ne quid nimis."

UNIVERSITY COLLEGE HOSPITAL: ITS NEEDS AND ITS CRITICS.

NOTWITHSTANDING strenuous efforts on the part of their supporters the financial condition and prospects of the metropolitan hospitals, with very few exceptions, are still far from satisfactory. In the case of several the outlook is eminently discouraging. Most of our readers will have seen the accounts recently published with reference to the wards at University College Hospital, where the net result of necessarily heavy expenditure and a diminished income has been the closure of 50 out of 210 beds. During the present year the funds of public charity have certainly been taxed to an unusual degree and this partly in connexion with the collective interests of the hospitals themselves. As yet, however, the Prince of Wales's Fund, which must have withdrawn a portion of the sums formerly subscribed for more strictly local objects, is not available. Meanwhile expenses accumulate. It is to be feared, moreover, that in the case of University College Hospital the very munificence of a benefactor has by a singular misunderstanding become in some degree a cause of deprivation. Early in the present year Sir John Blundell Maple came to the help of the hospital with a princely contribution of £120,000. A not unnatural impression appears to be prevalent that this amount is intended to relieve the pressure of working expenses and that consequently the public purse may for a time be best employed in meeting claims elsewhere. We hasten to correct this erroneous impression. Sir John Maple's liberal gift was offered with an entirely different object—namely, the rebuilding of part of the hospital which has long been in such a condition as greatly to impair its utility as a house of treatment for the sick and hurt. No part of the donation is designed for the actual cost of treatment. In addition to this fact it is to b noted that the falling off in ordinary subscriptions during the present year, no doubt on account of the causes we have already indicated, has been very great. It follows that the most stringent economy is imposed on all entrusted with the management of the hospital. Many suitable cases must be refused admission and none may remain in the wards a day longer than is essential to their safe removal. It is impossible to allow for any period of convalescence. In this connexion the history of a man who was recently allowed to leave the hospital and whose case, a medico-legal one, has been well ventilated in the daily press is of particular interest. The patient who was consigned to the care of the police authorities on the express understanding that he required rest and that his appearance in court if allowed must be merely nominal was removed accordingly and after an interval of detention elsewhere was called upon to appear before Mr. Curtis Bennett at Marylebone Court. The observations attributed to Mr. Bennett on this occasion, however they may reflect his own disappointment at the man's condition, were, we do not hesitate to say, not less unjust towards the hospital than injurious to its interests. They show that Mr. Bennett entirely failed to appreciate the circumstances under which the patient was allowed to be removed and the conditions entered into with the police when he was discharged. There is, we fear, no reason to doubt the accuracy of the expressions reported to have been used respecting the hospital. As such they amount to an imputation of neglect. As such they are equally damaging and unfounded. We are willing to allow that they were

Digitized by Google

used in a moment of irritation and not deliberately, but this fact does not render their repudiation the less a point of justice and a privilege of honour.

THE CONDITION OF THE ARMY AND ITS PROPOSED INCREASE.

THE next session of Parliament will be productive of several very important measures, not the least among them being that for the proposed increase of the army. After the series of letters that have appeared in the press from Mr. Arnold Forster, Lord Wantage, Sir Arthur Haliburton and others too numerous to mention, and the various speeches that have been delivered on the subject there will be no lack of material for important debates on the condition of our military forces, War Office administration, and army reform. Our statesmen and the nation generally will have to recognise that ours is a voluntary service army and to count on the fact that as we have not conscription and, what is more, are not likely to get it, the army must be content to compete in the labour market with other sources of employment. This means money for one thing and army reform and improved chances of employment for soldiers who have served their time for another. There cannot be a river without water or an army without recruits. Everything turns on that. To obtain recruits of the right stamp they must be paid a proper wage, the system of stoppages must either be altogether cancelled or altered, many irksome and unnecessary things connected with a soldier's life in barracks will have to be removed or modified, and, whilst all necessary discipline is maintained, the army must be put more on a level with the advances and requirements of life in the present day. The existing system of recruiting, too, needs to be thoroughly re-considered and popularised. Those medical officers who have had large experience of recruiting could no doubt afford some valuable information in this respect. We want better buildings and rooms more conveniently situated for the examination of recruits.

THE SCHOLAR IN MEDICINE.

THE annals of medicine contain the names of many who were not only brilliant lights in the calling to which they belonged but who were also possessed of that cultivation and mental training in other directions which make the scholar. It was a happy thought therefore of Dr. J. M. Da Costa, who recently delivered the inaugural address at the opening of the Harvard Medical School, to pass in review the names of members of the profession who have distinguished themselves in the broad fields of learning other than in their own line. In a sense all successful medical men must be scholars inasmuch that they are always students but Dr. Da Costa's address dealt more particularly with the men who while actively pursuing their profession and who were learned in it were not learned in it alone. Beginning with recent years the names which at once suggest themselves are Adams with his admirable translations of Hippocrates and of Paulus Ægineta; Greenhill, of Oxford, deeply learned in Greek and Arabic lore; Bussemaker and Daremberg with their Oribasius and other editions of Greek and Latin classics; and Littré the lexicographer and the learned editor of Hippocrates. Going back a century or two we find Linacre, Court Physician to Henry VIII. and founder of the College of Physicians, who had Erasmus among his pupils; Caius, Physician to Queen Elizabeth; Locke, Sir Thomas Browne, and Rabelais. Later came Galvani, Linnæus, Berzelius, Thomas Young (one of the first to interpret the Egyption hieroglyphics and who amongst his other accomplishments was master of Latin, Greek, Chaldee, Arabic, Syriac, Hebrew, Persian and Samaritan), Joseph Black, Gray, Owen, Agassiz, Leidy, Huxley, and Helmholtz, too, are all well-known names. Then there are the men who have been famed in their profession as well as being scholars. Perhaps the most conspicuous is Harvey "whose style is so limpid and clear that whatever he states becomes at once a demonstration and grace and propriety mark every utterance," the Cambridge scholar all his life as well as the great physiologist and physician. Sydenham too and Boerhaave, Haller, Mead (a Mæcenas in literature and art), Morgagni, Andral, Laennec, and Rush, will ever be remembered. This does not by any means exhaust the list of scholars who have been medical men or of medical men who have been scholars but they are some of the most prominent of those whose names are emblazoned on the roll of fame. It will be noticed that although, strictly speaking, these have not all been medical practitioners yet they have been eminent in some particular branch of medical knowledge. To mention the names of the living would be invidious but of those who have quite recently passed away the names of Simpson, Brodie, Watson, Latham, John Brown of Edinburgh, Trousseau, Malgaigne, Sée, Dunglison, Billroth, Hyrtl, and Wendell Holmes will always be associated with the title of scholar. It is not to be expected that everyone can equal or even approach the accomplishments of these men but the love of intellectual cultivation is widespread in the profession and ought to be encouraged. The practical bearings of scholarship in medicine are admirably summed up by Dr. Da Costa—power of expression and the critical judgment of a trained mind. "He" [the scholar] "was never more needed than now when every atom of discovery is heralded as of prodigious importance and as sure to influence immediately the laws of the universe (*sic*). ..... It is the scholar whose knowledge teaches him to appreciate correctly the different fads and 'isms' which are constantly cropping up and which he recognises as old errors with new faces."

PERSON *v.* PROPERTY.

AT the Clerkenwell Police-court on Dec. 3rd Henry Abbenhausen, of 134, Lever-street, St. Luke's, was summoned for having in his possession in preparation for sale 91 lb. of beef, mutton and pork unfit for human consumption. Mr. Horace Smith fined the defendant £20 and 2*s.* costs. At the same court Charles Clarke, aged sixteen years, and William Bunyan, aged sixteen years, were charged with assaulting Ada Fry and Rachael Welsh. The prisoners belong to a gang of roughs and on Dec. 2nd attacked the women, Bunyan striking Fry in the face making her nose bleed, while Clarke struck Welsh in the mouth knocking out a tooth. Mr. Horace Smith, as reported in the papers, said to the prisoners: "I must do something to stop this ruffianism; the only thing that holds me is your youth. You go about in gangs assaulting and terrorising poor women. It is perfectly shocking." After this admirable exordium Mr. Smith continued: "I ought to send you to prison, but having regard to your youth I will order you to pay 40*s.* each; in default a month's imprisonment." "Do you know I shall have to give you a good hard knock!" as the Rev. Robert Spalding remarked. What is the use of fining young blackguards of this sort? They will not pay the fine themselves. What is needful is a sound birching for we are compelled to agree with Mr. Smith that prison is not a helpful place, but if the law does not allow this class of offender to be birched it should be altered. Now let us take another class of case at another court. On Dec. 4th Benjamin Nordheim, a baker, of 141, Commercial-road, was fined the handsome sum of £417 17*s.* for allowing his premises to be used for the purpose of betting. This is wholesome but surely a man who keeps stinking meat presumably for the purpose of selling it as food or scoundrels who go about assaulting respectable passers-by should be

Digitized by Google

punished equally or even more severely. We are glad to note that upon Dec. 6th Mr. Curtis Bennett sentenced two roughs to two months' hard labour each for knocking down and kicking a man in the Edgware-road. If they had only stolen something from him they could have been soundly flogged as well.

TUBERCULOSIS IN CATTLE AND THE SLAUGHTER-HOUSE QUESTION IN THE UNITED STATES.

A CORRESPONDENT in America writes: "The question of tuberculosis in cattle as a means of spreading that disease has for a considerable time been occupying the attention of medical and scientific men in the United States. The danger resulting from the consumption of milk procured from diseased cows is probably more fully recognised in America than in any other country of the world Denmark alone excepted and in very many of the large towns stringent regulations are in force to ensure as pure a milk-supply as possible. So grave a menace to public health is the prevalence of bovine tuberculosis in New York State that the committee on tuberculosis appointed by the Legislature of 1895 virtually recommended the destruction of all cattle affected by it. That typhoid fever, diphtheria, and cholera can be, and often are, transmitted by the agency of milk is now an undisputed fact. In regard to the transmission of tuberculosis by the same means opinions are still somewhat divided, the English being specially rather sceptical on that point. Their standpoint, however, is quite a logical one as they do not hold with the extreme views advanced by American bacteriologists in regard to the contagiousness of tuberculosis. Nevertheless the supporters of the theory that the germs of tubercle transmitted by diseased cattle and other animals will under certain conditions infect human beings have many strong arguments on their side. A striking object lesson in support of this contention has lately been afforded in Kansas, and if the facts have been correctly reported should go far to prove the case for the upholders of the transmission theory of tuberculous contagion. For some time past a suspicion has existed that many of the cows composing the herd at the 'Kansas State Agricultural College' were infected with tuberculosis. Things went rapidly from bad to worse and when two or three of the cattle tenders were taken ill and one died the authorities took alarm and a committee of inquiry was instituted who after investigating published a report. In this report it is stated that a large shorthorn cow was killed and examined by the college veterinarian, who found that the lungs of the cow were a mass of tubercles, that the pulmonary and costal pleuræ were covered with tubercles, nd in fact that the entire entrails were diseased. Further, that from the appearance of the entire herd of fifty-eight cows and from the results of the tuberculin test the conclusion was warranted that all of them were infected with tuberculosis. The committee state in their report 'that in all probability the sheep and hogs are also infected, the barn and the yard and the feed lots having in their opinion been for years occupied by animals seriously affected with tuberculosis and being at this time little less than a pest-house and grounds, dangerous to both animal and human life.' When the fact is taken into consideration that something like one-seventh of all deaths is due to tuberculosis and that cows are very subject to the disease identical with that found in man the importance of studying animals in this connexion should not be under-estimated. In America Dr. Ernst, of Massachusetts, on the evidence of thirty-nine veterinarians representing seventeen states and reporting on 3000 cattle, gives 18 per cent. tuberculous and 8 per cent. suspicious. Dr. Deschwemitz, of North Carolina, says that in many cases from 50 to 70 per cent. of the dairy herds examined were found to be infected and in one of these 50 per cent. had tuberculosis of the udder. There is a growing opinion both in England and America that to the insanitary state of most of the slaughter-houses is due transmission of many diseases. Ch. Wardell Stiles, Ph.D., Zoologist, Bureau of Animal Industry, U.S. Department of Agriculture, says 'that slaughter-houses, more particularly those in the country, are centres of disease, and naturally the poorer the condition of the premises the more dangerous they are. These facts will appear clear if one considers what takes place at one of these houses. Even if only a few animals are slaughtered each week the total number may amount to several hundreds during the year. Some of the animals are surely diseased. At least one of the hogs has trichinosis and when the offal of this trichinous hog is fed to hogs which are raised upon the grounds the latter cannot escape infection with trichinæ. But that is not all. The slaughter-houses are often overrun with rats; the rats feed on the offal and when feeding on the offal of a trichinous hog they likewise cannot escape infection with trichinæ.' Dr. Stiles then goes on to show that not only trichinosis but echinococcus disease, 'staggers,' wireworm, and other troubles caused by animal parasites, as well as tuberculosis, hog cholera, swine plague, and other bacterial diseases are disseminated by means of dirty slaughter-houses. The result of the investigations of Dr. Stiles agree in the main (so far as the spread of consumption is concerned) with the conclusions arrived at by the Royal Commission on Tuberculosis in 1895. Without doubt the report of the Commission now sitting will when published throw much fresh light on this subject and will help to clear up many disputed points. At least, it is now agreed on all hands that the question of slaughter-houses should be thoroughly looked into and a sweeping reform in their management should be instituted."

REMOVAL OF A FOREIGN BODY FROM THE TRACHEA BY INTUBATION.

AT the meeting of the Société Médicale des Hôpitaux of Paris on Oct. 29th what appears to be the first case of removal of a foreign body from the trachea by intubation was related by M. Sevestre for M. Bonnus. A child, aged five years, put a bead in her mouth which passed into the larynx. Attacks of suffocation with cough lasting for about an hour and terminating with bloody expectoration occurred from time to time. During these at the end of expiration a distinct sound could be heard which appeared to be due to the shock of a foreign body. At the end of a month the child was admitted to hospital; at the time there were no symptoms. On the third day whilst she was being lifted a violent attack of suffocation—the fifth—occurred. Immediate intervention was imperative. As the foreign body was moveable the idea that it might be expelled after intubation occurred and that if it were large enough to be arrested in the tube it could be removed with the latter. To facilitate expulsion a tube for a greater age—that of seven years—was selected and easily introduced. A fit of coughing was immediately produced; another followed in three minutes, during which the body—a fragment of a glass bead—was expelled. Lest other fragments might be present the tube was retained. Only mucus containing black powder—débris of the bead—was expectorated. The child being quiet the tube was removed at the end of ten minutes. M. Sevestre pointed out that two conditions were necessary for success—mobility and moderate size of the foreign body. In this case it was slender, measuring one centimetre by three or four millimetres. The only case presenting any analogy to this, but one also very different, was reported to the International Medical Congress.

Digitized by Google

at Moscow by Bokay. Upon a child aged seven months, having some egg-shell impacted in the larynx, intubation was performed to break up the fragments which were expelled not through the tube but after its removal. The method of M. Bonnus certainly deserves a trial in similar cases; it is less serious than tracheotomy which can be performed in case of failure.

A CORRECTION.

IN a leading article which was published in THE LANCET of Oct. 16th the following words occurred: "Alderman Cooke, chairman of the Hospital Saturday Fund, said emphatically to our Commissioner: 'A subscription to a fund, whether it be weekly or yearly, gives no right whatever.'" It has been pointed out to us that the words thus attributed to Mr. Alderman Cook were really used by Mr. W. T. Smedley, the honorary secretary of the Birmingham Hospital Saturday Fund; and we have been referred by Mr. Smedley to an article written by him some four years ago in *Forward*, the official journal of the Birmingham Hospital Saturday Fund, where the phrase occurs. We are sorry for the error, for which, we may add, our Commissioner was in no way responsible.

PROPOSED MONUMENT TO THE LATE BARON SIR FERDINAND VON MUELLER, K.C.M.G., M.D., F.R.S., ETC.

BY the death of Baron Sir Ferdinand von Mueller at South Yarra, Victoria, on Oct. 10th, 1896, the scientific world lost one of its most erudite and industrious professors. As Government botanist he did some most painstaking work and it is gratifying to note that his supplemental volume of the "Flora Australiensis" which he was preparing for the press at the time of his death will be published by his executors together with two volumes on his administration as Director of the Botanical Gardens, Victoria, with a biography and complete bibliography of his writings. It is also intended to erect over his grave in the St. Kilda Cemetery a monument of grey granite twenty-three feet in height surrounded by an ornamental iron railing. Subscriptions are earnestly requested and will be received by the Rev. W. Potter, "Vonmueller," Arnold-street, South Yarra, Victoria, Australia.

A WONDERFUL INVENTION.

A SYNDICATE has been started with a capital of £5000 in £1 shares under the title of the "Ditcham Divinometer Syndicate, Limited." According to the prospectus the object of the association is "to acquire from Dr. Ditcham, the inventor, an instrument known as the 'Divinometer' and his patent and other rights therein." We also learn from the same authority that "this invention consists of a novel machine of simple construction whereby it is claimed that the psychic force of the individual can be gauged and the character of his will power determined," and are further modestly informed that "this discovery is as unique in its way as the Röntgen rays." The directors of the concern are Mr. Elphinstone Thorpe, Mr. Louis Hemmington Pegler, M.D. Edin., Mr. Duncan Cecil Smart-Melhuish, and Mr. William Vooght Ditcham, dental surgeon. It would have added immensely to the excitement that a discovery of this magnitude—the equal of skiagraphy—cannot but arouse if the promoters had appended an explanatory note on psychic force for the benefit of their prospective shareholders, and they might also have advantageously furnished a little information as to the ways and means by which it is proposed to make the speculation commercially successful. Ordinary ignorant people will be sure to want to know whether psychic force is a desirable possession or one to be mitigated by medicine. Perhaps the syndicate hope to gain fees from employers on the look-out for assistants. It is not difficult to imagine a druggist, for instance, anxiously awaiting the verdict as to the psychic force of a probationary pill-manipulator or a dressmaker on thorns while that of a prepossessing employée is being tested. But supposing the examinee had more will power than the examiner how would the divinometer act? It is really most regrettable that more ample information has not been afforded.

ISO-KREATININE.

A NEW nitrogenous substance differing from kreatinine in various particulars but especially in having a yellow colour has been obtained by Dr. Thesen of Christiania from the muscles of the codfish. To isolate it the dried muscle is infused in a large quantity of water to which a few drops of chloroform are added to prevent putrefaction. The vessel is set aside for the muscular tissue to subside and the supernatant fluid is boiled down to half its bulk. The albumin which is thus coagulated is removed with a spoon and the fluid is filtered and evaporated till the salts begin to make their appearance. The extract is mixed with its own volume of alcohol and allowed to stand to permit the subsidence of gelatin and inorganic salts precipitated by the alcohol. The alcohol is then distilled off when the yellow crystals of iso-kreatinine often make their appearance. On further addition of alcohol and purification with boiling water the iso-kreatinine can be collected in quantity in the form of small, delicate, shining, yellow laminæ. Dr. Thesen obtained about one gramme of iso-kreatinine from one kilogramme of cod's flesh, the actual quantity present being probably considerably greater. Its taste is bitter with an unpleasant after-taste. At a temperature of about 230°–240° C. it decomposes and at a somewhat higher temperature burns. It does not rotate the plane of polarisation. Its rational formula seems to be $C_4H_7N_3O$. It is therefore isomeric with kreatinine. Its reaction is alkaline and it forms well-defined salts with acids. It would be interesting to know whether this new body reduces alkaline copper solution

DR. YERSIN AT BOMBAY.

DR. YERSIN'S report on his late visit to Bombay is published in the *Archives de Médecine Navale et Coloniale* for November. He arrived on March 5th, 1897, having with him a very limited supply of serum which had been prepared by means of dead bacilli. If used the first day of the declared disease he found that thirty cubic centimetres were sufficient to effect a cure but on the second day four or five times as much was necessary. Most unfortunately from every point of view M. Pesas, the director of the laboratory at Nhatrang, died shortly after Dr. Yersin's departure and there was consequently some delay in obtaining a fresh supply of serum, for M. Roux in Paris "was not yet ready." Dr. Yersin treated 17 cases on the first day of the disease with a mortality of 12 per cent.; 17 on the second day, mortality 35 per cent.; 12 on the third day, mortality 50 per cent.; and 4 of longer standing, mortality 75 per cent.; the average death-rate on fifty cases treated being 34 per cent.—a very great improvement on the general ratio which among natives amounted to 85 per cent. We recently mentioned Dr. Bonneau's views regarding the relative efficiency of the anti-plague serums when prepared with living and dead microbes.[1] Dr. Yersin now confirms the statement that the intravenous injection of living cultures produces a more active serum in a shorter time but the process is so deadly to the horses, killing quite half of them, that he was induced to devise the second

[1] THE LANCET, Oct. 16th, 1897, p. 995.

Digitized by Google

method. No one can, of course, deny that expense is a major consideration in most things, but it is nevertheless regrettable that human lives should have to be sacrificed on account of a little "filthy lucre." At Amoy Dr. Yersin's death-rate was only 7·6 per cent., or not much more than half his best results in Bombay, and nearly one-fifth of his average mortality in the latter city. The course adopted by the Indian authorities for the suppression of the plague seems to have met with Dr. Yersin's unqualified approval, for he gives it as his opinion that precisely similar measures strictly applied would suffice with the aid of preventive inoculation for the rapid extinction of an epidemic of the disease in any French territory. With regard to prophylaxis Dr. Yersin found that a small injection of serum (ten cubic centimetres) protected a healthy person from the plague during a period of between ten and fifteen days and that a second injection would then prolong the immune condition for the same length of time. On his return to Nhatrang the distinguished French investigator was fated to experience the truth of the proverb that misfortunes never come singly. In addition to the irreparable loss already mentioned an epidemic of anthrax had broken out among the laboratory horses, but happily the officer in charge, M. Fraimbault, proved himself capable of dealing with the emergency.

THE WORSHIPFUL COMPANY OF PLUMBERS.

SPEAKING at the recent annual banquet given by the Worshipful Company of Plumbers at the Saddlers' Hall the Lord Mayor (Lieutenant-Colonel H. D. Davies, M.P.) dwelt upon the grave responsibility that devolved upon the plumber in that the lives of so many of his fellow creatures depend upon the conscientious execution of his work. He also warmly supported the Plumbers Registration Bill and deplored that such a useful measure should become involved in party strife. In his reference to the opposition offered to it by trade unionism and in the remarks made later by the Lord Provost of Glasgow on the iniquity of accepting tenders for work of this nature only because they were cheap the source of much bad plumbing was revealed. The Lord Provost justly held that such tenders had proved to be the very dearest that could be got. He said: "When I speak of the dearest I do not refer only to money but to human lives. There is nothing cheap in money if the lives of those we love best and have charge of are endangered." In every trade this mania for so-called competition in order to reduce cost is invariably the parent of one or the other of two grim offspring either of which is fruitful for evil. The first is "the sweating system"; the second "modern trade unionism." The former is an attempt on the part of the employer to secure orders by reducing the cost of production, using all means to this end, legitimate or otherwise, and is prolific of untold misery. Hence come all things cheap and nasty, from jerry buildings to shoddy, slop-made clothes and rickety furniture. The hidden work of the plumber presents a favourable field for operations under this head. The latter, "modern trade unionism," is the malignant growth of a very natural and proper combination on the part of those employed to resist such oppression and produces tyranny in its worst form, strikes, lock-outs, and increased cost of production, individual freedom and with it all real competition between the actual producers being strangled by the rules of the union. Thus the object aimed at—viz., reduction of cost—is ultimately defeated by the very means used for its attainment. Competition is productive only of good up to the point where individuals exercise their ability in contending to produce an improved article at the lowest possible price. It ceases to be aught but evil directly falsehood is somewhere introduced into the struggle. Ignoring its often too obvious presence will not relieve us from the penalty attached to it. The Plumbers' Company is certainly doing a good work. The Master, Alderman Richard Hind, himself a plumber, stated that in 1884 classes for scientific, practical, and technical instruction only amounted to five establishments with some two hundred students. There were in 1896 two hundred classes established and over three thousand students. The meeting together of the masters and men in connexion with this subject of education under the auspices of the Plumbers' Company should also do much to promote a better understanding throughout the trade.

THE DANGERS OF CHRISTENING.

AT the conclusion of a series of inquests held at the St. Pancras coroner's court a juryman remarked that in two of the cases children had died from pneumonia after having been taken to church to be christened, and he thought that mothers ought to be cautioned against taking very young children out into the cold for such a purpose. The coroner said that he did not think that if the children were well wrapped up taking them out would harm them, but he believed that if the parents chose the clergy would go to the house to perform the baptism. Of course they would if they were satisfied that it was a case of emergency but otherwise private baptism is forbidden. For the matter of that lay baptism, provided that the right matter and words are used, is perfectly valid, but this again is only to be used in extreme emergencies. One improvement we might suggest is that the rubric commanding baptisms to be performed in the middle of the office of mattins or evensong should be done away with so as to shorten the length of time that the child would be out and for the convenience of the godparents, and we would also impress upon the clergy the necessity of having the water warmed. Baptism it is true is seldom or never administered by immersion but even when affusion is used the contact of cold water with a child's head might injuriously affect one with an already sufficiently low power of resistance. But if sufficient care as to clothing is taken the mere conveying of the child from the house to the church should do no harm.

THE DENTAL HOSPITAL OF LONDON.

THE staff and present and past students of this hospital must have been gratified to be informed authoritatively on the occasion of their annual dinner, which was held in the Whitehall Rooms of the Hôtel Métropole on the 4th inst., of the progress that is being made in connexion with the building of the new hospital. The site is contiguous to the old building, which, with a deceptively large front, is in reality utterly inadequate to the needs of both patients and students. The old hospital is an extremely narrow building and affords no convenience or accommodation in accordance with the increasing demands upon the energy and skill of the staff or for the educational purposes of the institution. Mr. F. A. Bevan, one of the trustees, in his response to the toast of "The Hospital," stated that some delay had occurred in clearing away the vested interests in the property in the new site, but now they were within measurable distance of the commencement of building operations. The plans of the new building showed that when finished it would be an adequate hospital and school fully equipped, and with offices and appointments thoroughly in accordance with modern advance in dental treatment. Mr. Watson Cheyne referred to the progress which dental surgery had made and congratulated the authorities on having decided upon a step which was to give increased facilities to the study of the various scientific subjects such as bacteriology, metallurgy, &c., now of necessity included in the dental curriculum. The chairman, Mr. A. S. Underwood, in proposing the toast of "The Past and Present Students," expressed the opinion that in view of

Digitized by Google

the increased demands upon the time and attention of dental students they should be careful to organise a system of recreation for the advantage of both body and mind. Mr. C. S. Tomes, F.R.S., proposed the health of "The Chairman" and briefly referred to the rapid progress which the school had made.

THE QUESTION OF REGULAR ATTENDANCE AT BOARD SCHOOLS.

A CORRESPONDENT writes to us upon this subject, one not in any way new but none the less important. It is certainly a fact that children are sent to school when they are quite unfit in themselves to attend; moreover, there is no doubt that they are sometimes sent from houses where infectious disease exists without this fact being made known. The School Attendance Committee in its eagerness for equality of treatment is becoming a veritable Procrustes. The children whether able or not must lie on the educational bed and if they will not fit they must be made to fit. The Education Department and the School Board between them lay a most grievous burden on the backs of both children and parents. Compulsory primary education is a good thing and should by all means include swimming, cookery, needlework, and house-work, subjects which are taught at the present moment, so that perhaps in time it will be possible for the average householder to find a servant who will know how to set a candle or clean a window. But besides these subjects the Board teach over thirty other different things most of which can by no manner of means be described as primary. No wonder that the wretched children are ground in the mill; let the Board diminish its curriculum to a third of its present size and then an occasional absence will not matter so much. It is difficult to see how a Board can be punished. It cannot be fined under the Public Health Acts for exposing cases of infectious disease for the fine would simply fall upon the ratepayers, but Boards must not be allowed to foster the spread of infectious disease owing to a fatuous craze for regular attendance.

OSTEO-ARTHRITIS CAUSED BY PNEUMOCOCCI.

ARTHRITIS, due to the presence of pneumococci in the joints, is now one of the recognised complications of pneumonia. At a recent meeting of the Société Médicale des Hôpitaux of Paris Dr. Fernet called attention to a peculiar form which differed entirely from the ordinary and purely articular. Only two cases had been observed and the sterno-clavicular joint was the one attacked in both. The onset was sudden and attended with severe pain, considerable swelling soon followed, but redness was slight or absent. The swelling was not due to effusion into the joint (as demonstrated by puncture), but to œdema of the peri-articular cellular tissue. The articular surfaces were rapidly eroded, so that crepitus like that of a fracture was soon felt, as early as the thirteenth day in one case. Dr. Fernet regarded this sign as characteristic. The duration of the disease was long because fibrous ankylosis, the natural termination, took some time to develop. In one case it was more than two months. The treatment followed was immobilisation of the joint. The other case terminated fatally at the end of three weeks. A necropsy was made. The peri-articular cellular tissue was infiltrated with serum; the muscles looked uneven and pale and showed purulent striæ; the ligaments and cartilages were completely destroyed; the articular surfaces were represented by rugged surfaces of spongy bone. There was no effusion in the joint and a few drops of serous fluid were obtained with difficulty which yielded pure cultures of the pneumococcus. In this case there was also pulmonary and meningeal infection. Dr. Fernet called attention to the analogy of the osseous lesions to those observed in the arthropathies of locomotor ataxia both in their nature and clinical evolution and suggested that possibly the latter was also due to a microbial cause favoured perhaps by trophic defects.

THE PLAGUE IN INDIA.

WE much regret to say that the latest intelligence from India regarding the plague is not satisfactory. The disease shows no signs of abatement in Poona. The cantonment is now entirely under the charge of the military plague management. Privileged segregation has been abolished and there have been no disturbances or expressions of dissatisfaction. The public health statistics in Bombay show that the total mortality is very high although it has somewhat declined. There are still numerous cases of bubonic plague occurring—especially in the insanitary districts where it originally appeared. At Sholapore, Belgaum, Kotri, near Kurrachee, in Sind, at Shanderkhard in the Jullunder district of the Punjab, and other places we read in the Anglo-Indian journals of the appearance of cases. The India Office in this country has sent out a number of medical men and nurses for employment during the prevalence of the epidemic and the local governments of India are actively engaged in enforcing measures for the repression and limitation of the disease. Although there is no doubt that local causes and environing conditions have a good deal to do as fostering the epidemic the practical fact to be grasped is that the plague is spread through human beings: it is the individual and not the locality that is in the first instance infected. Some interesting details as to the spread and prevention of plague will be found in another column. Bacteriological researches support the view that we have to deal with a contagious disease depending upon a specific cause.

ARE CIGARETTES INJURIOUS?

WE have been favoured with an "advance" abstract of a paper appearing in the number for December of the *Medico-Legal Journal of New York*. It is entitled "A Brief for the Cigarette" and is written by Mr. W. H. Gerrison. While it disposes of a good deal of nonsense that is talked about the terribly poisonous nature of cigarettes and the dire harm resulting from their consumption it does not quite satisfy us upon the important point—the quality of the tobacco. We do not believe that tobacco is ever seriously sophisticated as with arsenic and opium, but we are pretty sure that very inferior kinds of tobacco and diseased tobacco disguised with certain scents are commonly the materials of which absurdly cheap cigarettes are composed. Small boys and even full-grown boys are not thus deterred from smoking them because these cigarettes afford them something at any rate to smoke in spite of the obvious "faking." In America two states—namely, Tennessee and Iowa—and two cities, Denver and Chicago, have legislated against the cigarette apparently on grounds that its excessive use and very rapidly increasing consumption had led to dreadful degradation of the physical as well as moral health. Excess in anything is always an evil and one it is difficult to check by legislation; but are the great majority to forego the honest and perfectly legitimate use of a thing because of the abuse practised by the few? We do not believe that where injurious effects do occur they are due to added toxic substances. Our own inquiries established this some years ago, both in regard to the tobacco and the fragment of paper in which the former is wrapped. They were both quite free from arsenic, opium or other monstrous additions. If the cities and states just mentioned would direct their attention to ensuring the supply of tobacco of unquestionable quality and purity, be it in the shape of cigar, cigarette or pipe tobacco, they would proceed, we

Digitized by Google

venture to think, upon a more rational line of action and secure the gratitude and esteem of the public. One result of this action at least would be to render impossible the sale of cheap and nasty cigarettes and thus some limitation would be put upon the excessive number consumed by almost every small boy met with at every turn in the street.

MEMORIAL TO THE LATE DR. F. W. BARRY.

A PRIVATE subscription has been opened among certain of Dr. Barry's friends and colleagues, Sir Richard Thorne acting as treasurer, with a view to the erection of a lych-gate for the burial-ground at Downe, Kent. The extension of the churchyard was a much-needed scheme in which Dr. Barry as a resident in the village took an active part, and he was one of the first to be laid to rest in the newly-consecrated ground. The provision of a lych-gate for the churchyard in which he took such interest will commend itself as a most fitting tribute to the memory of one whose distinguished services and sterling character secured for him the esteem and strong personal regard of all who were brought into contact with him. It was at first proposed that the cost should be defrayed by his immediate colleagues, but many others have expressed a wish to contribute and it has been decided to deviate from the original intention to that extent although no special appeal will be made.

AT the adjourned discussion on the Prevention of Enteric Fever to take place at the meeting of the Royal Medical and Chirurgical Society on Tuesday next the following speakers are announced amongst others:—Dr. J. F. Payne, Surgeon-Major-General Jameson, Dr. Kanthack, Dr. A. Macfadyen, Dr. Sims Woodhead, Dr. Edward Seaton, Dr. F. W. Andrewes, Dr. Corfield, Dr. Washbourn, Dr. Newsholme, Dr. Seymour Taylor, Dr. Little, Mr. Tivy, and Mr. Bokenham.

AT a meeting of the lecturers and teachers in the medical school of Guy's Hospital held on Dec. 6th, 1897, the following resolution was unanimously passed:—

That the medical school of Guy's Hospital earnestly request Her Majesty's Government to reintroduce into Parliament the London University Commission Bill of 1897 and to pass it into law during the ensuing session.

THE annual lecture under the Richard Middlemore Post-graduate Lectures Endowment will be delivered at the Birmingham and Midland Eye Hospital by Mr. H. Eales on Thursday, Dec. 16th, at 5 P.M. The subject will be Exophthalmos, its Causes and Treatment.

FOR the consideration of their report meetings of the Royal Commission on Tuberculosis were held at Whitehall-place on the 1st, 2nd, 3rd, 4th, 6th, and 7th inst., Sir Herbert Maxwell, Bart., M.P., presiding. A further sitting will be held in January next.

Pharmacology and Therapeutics.

HYPODERMIC INJECTIONS OF OXALATE OF POTASSIUM IN PHLEGMONOUS INFLAMMATION.

OXALATE of potassium being known to have the property of preventing or retarding the tendency of organic fluids to coagulate, it occurred to Dr. G. Cavazzani, the principal surgeon of the Civil Hospital in Venice, to utilise this property in the treatment of phlegmonous inflammation by injecting a 1 per cent. solution into the surrounding tissues so as to diminish the capillary engorgement and the plastic effusion which always exist there under these circumstances. The first case in which this plan was tried was that of a woman who had a large phlegmonous swelling which extended from the middle of the upper arm to the hand and which had been in existence for two months. The acute stage was passed and there were no collections of pus or patches of slough but the arm was stiff, swollen, red, hot, and painful. Ten injections were given into the cellular tissue around the affected portion, thirty minims in all being thus introduced. The next morning the swelling, the redness, and the pain had perceptibly diminished; the injections were repeated every three or four days and at the end of three weeks the patient was completely relieved. Subsequently Dr. Cavazzani employed this treatment in several other cases of phlegmonous inflammation with good results. Among them were two cases of phlegmasia alba dolens which rapidly recovered under the influence of the same solution, thirty to forty-five minims being introduced in ten or twelve points. In one of the cases two repetitions were sufficient; in the other three. Another case was that of a man who had undergone an operation for inguinal hernia and in whom three days afterwards inflammation of the cellular tissue of a somewhat alarming character began to appear. Thirty minims of the solution were injected in eight points situated beyond and around the circumference of the inflammation and the next day the inflammatory symptoms were found to have subsided. The only inconvenience resulting was a trifling amount of suppuration about two of the sutures of the wound. These injections of oxalate of potassium appear to be quite harmless as no sign of poisoning was observed in any of the cases. Whether the theory upon which Dr. Cavazzani based his employment of this salt be correct or no the fact remains that the results obtained by him are very encouraging and the treatment seems to be worthy of a trial by other practitioners.

AIROL IN THE OPHTHALMIA OF NEWLY-BORN CHILDREN.

Airol having proved very useful in the treatment of gonorrhœa M. Ardin-Delteil, of Montpelier, was induced to make trial of it in a case of ophthalmia in a newly-born child, nitrate of silver which had been previously employed having appeared to increase rather than to diminish the intense inflammation. He applied a 5 per cent. airol ointment made with vaseline, leaving it in contact with the mucous membrane for twenty minutes and then washing it off thoroughly with a solution of boracic acid. After this an immediate improvement was manifest, the swelling and conjunctival secretion being greatly diminished by the next day when a fresh application was made. The treatment succeeded in preventing suppuration and in a week's time a successful result was achieved.

THE WORKHOUSE INFIRMARY NURSING ASSOCIATION.

A WELL-ATTENDED meeting of the Workhouse Infirmary Nursing Association was held on the 2nd inst. in St. Martin's Town-hall, to consider the following resolution:—

"That the Executive Committee after long and careful consideration is of opinion that the time has arrived when the work of the Association must of necessity cease."

Mr. E. BOULNOIS, M.P., occupied the chair, and after making sympathetic allusion to the loss sustained by the Association through the death of its President, H.R.H. the Duchess of Teck, drew attention to the great work which the Association had done, not only in directing public attention to the terrible state of things which existed twenty years ago—a work in which THE LANCET had also taken a prominent part—but also in remedying such a state of matters, and inducing boards of guardians to appreciate the value of trained nursing. He also referred to the benefit which had accrued not only to the poor but also to the ratepayers—facts of which he had personal cognisance by his long association with the Marylebone Board of Guardians.

Miss WILSON, the honorary secretary of the Association, then read a brief statement showing that during the eighteen years the Association had been in existence over 1200 applications had been received and nearly 800 nurses supplied. The applications for nurses from boards of guardians had steadily increased during that period, but unfortunately the supply of suitable women for training had steadily diminished.

The resolution was moved by Mr. BOUSFIELD, a guardian of Kensington and a member of the working committee, and seconded by Lord MONTAGU of BEAULIEU.

Digitized by Google

Many speakers, delegates from boards of guardians in different parts of the country, spoke on the subject and expressed the grave and serious regret which they felt that the Association should give up its good work. Several of them, including Miss Brodie Hall (Eastbourne), Mr. Shepherd (St. Pancras), Miss Lawes, and the chairman of the Cheltenham Board of Guardians, went so far as to suggest increased subscription on the part of the guardians so as to meet one of the difficulties, and affirmed that they did not know what they would do in country workhouses without the assistance of the Association.

The second resolution laid before the meeting by the Executive Committee was to the effect that the Association would continue for a time as a centre of information to guardians and nurses and for the maintenance of a connexion with the nurses and probationers still belonging to the Association.

Miss TWINING in support of this resolution pointed out that the real difficulty of the committee was the lack of suitable candidates for training and that the cause of this was undoubtedly the anomalous and difficult position in which nurses found themselves, especially in country workhouses. At the same time the Association felt that they were, in view of all the circumstances, altogether unable to deal with the matter in an adequate fashion, and it was hoped that when the Association ceased to attempt the work in their small and imperfect way it would result in its being done on a larger scale and more adequately either by the Local Government Board or by associated guardians. It was impossible for the Workhouse Infirmary Nursing Association to supply the 600 workhouses in England and the matter had reached a stage at which a private body was no longer able to deal with it. Responsibility must now rest upon the shoulders of the central board. The new Order, which was undoubtedly one of the achievements of the Association, finally did away with pauper nursing and created a demand for trained nurses, and some sort of State organisation must inevitably be formed to supply them in the same way as had recently been done for the Army and Navy. Miss Twining took grave exception to the use of the word "experience" in the new Order, instead of the word "training," because she could remember the time when all the old-fashioned drunken attendants in workhouses were in the habit of calling themselves "experienced" nurses. The Association had repeatedly asked for a State grant or some State recognition, but as it was not forthcoming it was impossible for a private philanthropic association to deal with the matter any longer.

Both the resolutions were carried.

THE ROYAL COMMISSION ON THE METROPOLITAN WATER-SUPPLY.

THE second sitting of the Royal Commission on the Metropolitan Water-supply was held in the Moses Room of the House of Lords on Monday last, Dec. 6th. All the Commissioners were present at the meeting. The London County Council and the water companies were represented by counsel and the Corporation of the City of London by the Remembrancer, Mr. Goldney. At the commencement of the meeting the chairman made an important announcement. He said: "We have decided not to reopen the questions reported upon by the Royal Commission presided over by Lord Balfour and, speaking generally, we accept the findings of that Commission." [1]

Mr. H. L. Cripps, the Parliamentary Agent of the London County Council, was again examined. He put in three tables giving a quantity of information on the subjects on which he had been examined at the last meeting. Table A, "showing the various areas in London under the Metropolis Management Acts, the companies originally authorised to supply water within those areas, and the manner in which Parliament has introduced and confirmed the number of competitive powers of supply in London." Table B, "showing certain areas actually supplied by the New River or Chelsea companies and the dates at which a fresh competitive supply by another company or other companies was authorised." Table C, "showing the dates of the Acts under which several metropolitan water companies were originally authorised to make charges for water and cases in which authorised rates have been reduced and the dates when the existing scales of charges were fixed." A large map showing the area of distribution of the metropolitan water companies was hung on the walls. This map, like those which have been recently published in THE LANCET, showed the sources of intake of the various companies and gave the course of the chief mains in the case of each company. Mr. Cripps was examined at some length by the chairman concerning the information given on the tables and particularly with regard to the competition between the different companies. He pointed out that Marylebone, which was at one time supplied by the New River and Chelsea companies, was afterwards supplied by the West Middlesex and Grand Junction companies. The chairman inquired as to what precise evidence there was that Parliament had encouraged competition between different water companies. He asked whether when Acts authorising new supplies were passed there was any direct reference in any Act bearing on the question that a new supply was needed because the then existing supply was bad in quality or because the inhabitants were charged too much. Mr. Cripps could not point to such an instance, but said that the Vestry of Marylebone had supported the West Middlesex Bill on the grounds that the quality of their water-supply would be improved and that they would receive it at higher pressure, but he could not name any street in which the mains of two companies were actually supplying water at the same time. The chairman asked on what he founded his statement that the West Middlesex Company had ousted the Chelsea Company, and in reply Mr. Cripps pointed out that at one time Marylebone was supplied by the Chelsea and New River companies and that in the year 1806 their customers preferred to have a new supply which was said to be better in quality and for which they certainly had to pay less. Mr. Cripps could not remember any case since the passing of the Waterworks Clauses Act in 1847 in which Parliament had anywhere in the United Kingdom authorised a further supply of water in competition with the already existing supply.

The next question considered was the advantage which Mr. Cripps thought would accrue to the people of London by the purchase of the existing water companies by the County Council. The chief reasons given were as follows:—1. The purchase by the County Council would be a final settlement of the matter. (The present state of things resulted in a very great expense because of the numerous Parliamentary proceedings which took place and the amount of money

[1] The report of the Royal Commission which was presided over by Lord Balfour was published, it may be remembered, in 1893. It may be well to recall the terms of the Commission and to state briefly the conclusions to which the Commissioners came. The questions which the Commissioners were asked to determine were: "Whether, taking into consideration the growth of the population of the metropolis and the districts within the limits of the metropolitan water companies and also the needs of the localities not supplied by any metropolitan company, but within the watersheds of the Thames and the Lea, the present sources of supply of these companies are adequate in quantity and quality; and if inadequate whether such supply as may be required can be obtained within the watersheds referred to, having due regard to the claims of the districts outside the metropolis but within those watersheds, or will have to be obtained outside the watersheds of the Thames and the Lea?' The report described the area affected by the inquiry, gave some account of the histories of the water companies which supplied it and entered in some detail into the question of the probable future population of greater London. Statistics were given with regard to the amount of water supplied at the time and as to the quantity which would be likely to be required in the future. An account was given of the geological structure of the basins of the Thames and the Lea and the present sources of supply were considered in some detail. Various schemes suggested for future supply were briefly described and an estimate was given of the quantity of water which it was thought probable could be obtained from the deep wells. The important conclusions to which the Commissioners came with regard to the quantity of water which could be obtained and to the quality of that which was then supplied to London may be summed up as follows. With regard to quality the Commissioners were of the opinion "that the water as supplied to the consumer in London is of a very high standard of excellence and of purity and that it is suitable for all household purposes." With regard to the quantity the Commissioners came to the conclusion that a daily supply of 420,000,000 gallons could be obtained from the sources and by the methods mentioned in their report. This quantity was sufficient to supply thirty-five gallons a head to a population of 12,000,000 persons, "which is about three-quarters of a million in excess of the total population of Greater London, together with the outlying parts of water London will have become in 1931, even if the ratio of increase in the decennial period from 1881-91 is fully maintained." It will be seen that by accepting the findings of Lord Balfour's Commissions the present Royal Commission have greatly limited the scope of their present inquiry.

Digitized by Google

which was spent on learned counsel and surveyors.) 2. If all the water undertakings were under the same administration the public would have a better chance of bringing pressure to bear on those who administered the undertaking. (At present the offices of some of the companies were inconveniently placed—for example, that of the East London Company was situated in the City of London at some distance from the area actually supplied by the company.) 3. The water-rates at present charged were unequal in different parts of the metropolitan area; under one central authority a rearrangement of the amount paid could be more readily made. 4. Some organised local authorities ought to be responsible in the case of the water-supply because on its purity the public health so largely depended and in this connexion Mr. Cripps adopted the words as well as the argument of Mr. Chamberlain, who in supporting the Birmingham Water Bill spoke as follows: "I consider the grounds for transfer more strongly applicable to the case of water than of gas. The case of water is a question chiefly of health, whilst the case of gas is a question chiefly of profit, and it seems to me absolutely certain that what Professor Simon called 'the power of life and death' should not be left in the hands of a commercial company, but should be entrusted only to the representatives of the people. I think the supply of water should not be directly or indirectly dependent upon the profits of a private association. In the first instance the obvious duty of the directors of a private company is to consider the interests of the shareholders, and this necessarily, without any imputation on their *bona fides*, stands in antagonism in principle to the interests of the community at large."

The latter part of the sitting was taken up by an examination of the witness on the action taken by the London County Council with regard to the local authorities of the various areas surrounding their own sphere of influence. Mr. Cripps said that negotiations had been entered into with the Surrey County Council, the Croydon Corporation, and with the county councils of Kent and Essex. An agreement was arrived at with the Surrey County Council by which the London County Council would give over their claims to supply that part of the County of Surrey which was under the jurisdiction of the Surrey County Council. The chairman, however, stated that he was informed that the Surrey County Council were now opposed to the purchase of this water-supply. An agreement had been made with the Croydon Corporation. The Hertfordshire County Council would enter into no agreement nor would the County Council of Middlesex. The County Council of Essex wished also to manage their own affairs. The chairman asked Mr. Cripps whether he knew of any case in which water trusts covering several areas had been established and whether they were worked satisfactorily. In reply Mr. Cripps said that in the case of Belfast the water trust did not work well for it led to conflicts between the corporation and the water trust. Mr. Cripps was not in favour of the formation of a Water Board for London. As far as the County Council were concerned he said it was an impracticable scheme and that all the arguments which justified the London County Council in urging the transfer of the water undertakings to themselves would justify the surrounding local authorities in asking that a transfer should be made to them of their parts of the undertaking.

THE INDIAN FRONTIER CAMPAIGN.

SIR WILLIAM LOCKHART is fast carrying out the plan of his projected expedition and enforcing obedience on some of the recalcitrant tribes, but we do not hear that the Afridis are submitting to the terms offered to them. We presume that the campaign will be officially closed before long in view of the winter. It appears to be undoubted that some interesting documents have been discovered which throw a fresh light upon the causes of the general uprising of the frontier tribes. The Mullahs had been urging the chiefs of the tribes to join the present campaign alleging that the Turks had conquered the Greeks and were fighting against the English and that the Suez Canal had been closed, consequently the time was propitious for a successful revolt. It is of course greatly to be regretted that this tribal war has broken out at the present time, but the revolt having taken place the Indian Government was compelled to take action in order to punish the tribes and defeat the object they had in view; arguments about the past and future policy that had been or should be adopted had in the meantime to be deferred.

The Anglo-Indian papers are naturally full of descriptions and details of the expedition, but their news has been forestalled by the telegraphic summaries which have already reached this country. Owing to the number of sick that have arrived from the front and from the Mohman force and that in the Tochi Valley it is stated that the hospitals in the rear have been overcrowded and additional hospital accommodation will be required.

The opening of another hospital at Nowshera is urgently called for, an addition of 300 beds being probably required. The hospitals at Rawal Pindi are unable to accommodate any sick from Nowshera in consequence of having to provide for those from the Tochi Valley and Kohat, where also and at Gumbat additional accommodation had to be provided recently.

There had been a large amount of sickness among the troops in the Tochi Valley and the rifle brigade had suffered so much and lost so many men that it had returned to India. The 93rd Highlanders and the native troops had also had a good deal of sickness. The valley is known to be very unhealthy, but it had for military and strategical reasons to be occupied. The troops were exposed to considerable physical strain in their marches and were fatigued; the water was bad, the climatic heat and the changes of temperature were great, and the "sniping" at night also told on the force. The troops were frequently moved to new ground but did not throw off their sickness. In addition to malarial fever a severe form of dysentery was very prevalent and was fatal to many soldiers and led to a good deal of invaliding. The disproportionate loss of life among officers in the fighting that has taken place during the various operations on the frontier has been a subject of general remark. Apart from their greater exposure in leading their men it is probable that the difference in their uniform causes them to be singled out by the Afridi marksmen.

THE BATTLE OF THE CLUBS.

THE MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND AND MEDICAL AID.

"M.R.C.S." writes to us as follows:—

"The resolution carried by the Members of the College of Surgeons at the annual meeting re medical aid associations and touting is in my opinion a farcical one. In this district within a quarter of a mile of my surgery four associations exist who all tout: (1) Medical Aid Association, fee 1*d.* per week; (2) Medical Service Association, fee 1*d.* per week; (3) Provident Dispensary, fee ½*d.* per week (membership 13,000 at least); and (4) Maternity Society (average number of cases 700 per annum), fee 5*s.*; nurse 2*s.* 6*d.* extra."

This is certainly a most unsatisfactory state of matters. That any member of a learned profession should consent to bind himself down to be at the beck and call of anyone who likes to summon him at all hours of the day or night for the magnificent sum of 2*s.* 2*d.* per annum is simply scandalous. Such a man can set no value whatever upon his work and we are quite certain that no member of the club, whatever his trade, would consent to be at the service of a medical man to clean his windows or house, look after his gas-fittings or his water-supply, or even perform such unskilled labour as cleaning boots, knives, or carrying coals for twenty times the sum. We advise "M.R.C.S." to send in the names, addresses, and qualifications of the medical men attached to the institutions mentioned to the Council of the Royal College of Surgeons of England, who have promised to consider carefully any such specific instances when brought before them.

MANCHESTER MEDICAL GUILD.

The council of the Manchester Medical Guild has issued a circular to the practitioners of Manchester and the neighbourhood upon the subjects of Hospital Reform and Medical Aid. With reference to the first matter the council says that a joint committee representative of the medical charities and the medical societies of Manchester and Salford has been appointed to inquire into the alleged abuse of hospitals and to suggest remedial measures. Abuse doubtless exists, but

Digitized by Google

the committee cannot be expected to recommend any substantial reform without some clear and irrefragable evidence. As various medical practitioners most probably possess such evidence but feel doubtful about coming forward to give it the Medical Guild is prepared to act as intermediary between the practitioner and the committee and will submit to the latter any cases of abuse of which it may receive satisfactory evidence. All information will be communicated to the committee in confidence and the names of practitioners will not be divulged unless they wish it. Practitioners are therefore urged to send to the secretary of the guild any cases of abuse of which they have knowledge. "The Council of the Guild has recorded its disapproval of the practice of exacting fees from patients of the medical charities." This we suppose means disapproval of the system of pay hospitals and the like. As to medical aid the Council refers to a lately started branch of the National Deposit Friendly Society and points out that the profession ought in no way to lend their aid to this scheme, for (1) it means the interference of third parties between the medical man and his patient; (2) the fees are altogether inadequate and have been arranged without consultation with the medical profession; (3) there is no wage limit; and (4) the most likely people to join would be the thrifty, better-off people who are well able to pay the ordinary medical fee, while the poor and improvident would remain on the hands of the profession as now.

The Manchester Medical Guild ought, we think, to do good work. Its objects are shortly to organise the profession to secure united action and the coöperation of all for the common good. The annual subscription is 5*s.* and the secretary is Dr. Alexander Stewart, 12, Eccles Old-road, Pendleton, Manchester.

THE MEDICAL ACTS OF PARLIAMENT.

AT a meeting of the South-West London Medical Society held on Wednesday, Dec. 8th, Mr. Victor Horsley, F.R.S., gave an address on "The Medical Acts of Parliament: as they are and as they ought to be." Mr. T. A. IVES HOWELL presided.

Mr. HORSLEY said he had found that considerable misapprehension prevailed as to the exact powers the medical profession were accredited with as a body politic under the Acts of 1858 and 1886. The Act of 1858 put them into the position that they were registered practitioners of medicine and they alone were qualified practitioners of medicine. But this was not the view which had been taken by the legal advisers of the General Medical Council. They had now, however, been forced to take that view. Their previous contention was that the Acts only protected the title and did not protect a medical man in their practice. It had been held by the legal advisers of the General Medical Council that the diplomas of the corporate bodies were licences to practise medicine, but whatever they were in the past they were entirely altered by the Act of 1886 and 1858. The Act of 1886 says the qualifying examination shall be one in medicine, midwifery, and surgery held for the purpose of granting a diploma or diplomas conferring a right of registry. That was where the whole structure of the Medical Acts came in. So that in the eyes of the law the diplomas did not give the right to practise but the right to demand that the names of the holders of the diplomas should be placed on the Medical Register, the obvious inference being that any person not on the Register was liable to prosecution. The diploma given by a corporate body was therefore not a licence to practise. All that was wanted to do away with any doubt at all in the matter was a section added to the Act that only registered persons should be entitled to practise: the section to be followed by the penal clauses. By the Act no person could hold an appointment of any kind to any public body or friendly society without being a person registered under the Acts. Yet it had come to his knowledge that unqualified persons were placed as medical officers in public situations. He pointed out that the administration of the Acts were practically in the hands of the General Medical Council, but there was so much diversity of opinion that anything like concentrated action in administering the Medical Acts would always be difficult until the constitution of that Council was altered. He referred to the need of a one portal system and the power of the General Medical Council to bring about that desirable reform. From his own observation it would seem that the corporate bodies would not object to one professional examination although they might object to one preliminary examination. That would be beginning reform by placing the cart before the horse, but it would be better than no reform at all.

A discussion followed, in which the Chairman, Dr. ALDERSON, Dr. BATEMAN, Mr. JOSEPH SMITH, and others joined.

THE CYCLING EXHIBITIONS.

IN spite of the large number of accidents which occur during the cycling season the craze for "wheeling" increases and the large crowds which have daily visited the two great "shows" of the year, the Stanley and the National, seem to show that the interest in the pastime is likely to be still larger in the coming season.

At the Stanley Show which held its twenty-first annual exhibition at the Agricultural Hall from Nov. 19th to Nov. 27th little was to be seen that could be called novel, but some of the "gears," saddles, brakes, and accessories were worth careful examination. The Pyramid frame, manufactured by the Genese Cycle Co., places the rider exactly between the front and back wheels and would seem to be an improvement on the conventional form. Several new chainless gears were shown, but although they presented some obvious advantages over the ordinary chain and toothed wheel time alone can show their value. Most of them take the form of a revolving rod which is connected with the back wheel and bottom bracket by bevelled cog-wheels. Among the most ingenious of them is that known as the "La Gazelle" Link Motion Chainless Bicycle. The mechanism cannot be adequately described in a few words but the action is perfectly simple when seen. The appearance of this new gearing is similar to that of a draughtsman's pantograph. The "Protean" gear of the Whippet Cycle Syndicate enables the rider to change the gear at will—a decided advantage when travelling over roads which present frequent undulations.

The liability of nickel plating to become rusty has had the effect of stimulating inventors to produce a metal which while maintaining a high state of polish shall not have the disadvantages of nickel. "Kronard" metal has somewhat the appearance of silver and is stated by the manufacturers to be non-rusting and to be stronger than steel. It is claimed to be the strongest and whitest metal yet produced. A number of cycle parts are shown in "Kronand" such as hubs, spokes, rims, bells, foot rests, &c. "Hecunum" is another metal of similar description.

Saddles were to be seen in infinite variety. Among the most noticeable were the Pattison, which certainly goes a long way towards reducing perineal pressure, and the Henson. Wood's patent wire saddle which is constructed similarly to a wire-woven mattress and covered with a leather or felt cover would seem, as is claimed for it, to be cool, comfortable, and light.

Of the brakes the pneumatic which consists of a hollow bulb which being compressed forces air into a rubber chamber or pad and thereby expands this on the tyre has the advantage of being fixed over the back wheel. Williams's patent concealed brake, the rod of which runs down the steering post, appears to be a useful one. The Sawyer safety foot-brake is powerful in action but has the obvious disadvantage of necessitating the taking of the foot from the pedal.

Bowden's new mechanical movement for the transmission of power along slack wires as adapted to brakes is ingenious and likely to prove useful in many other directions. Mr. Bowden also showed a new brake which acts on the rim of the back wheel and, if it should prove as powerful in practice as its demonstration at the exhibition would seem to show it will, there is a great future before it.

As at the Stanley show so at the National show which closes to-day (Saturday), little is to be seen in the way of new machines—that is to say novel in design. Exception must be taken however with regard to "the Cantilever" (the Cycle Supply Association), the advantages claimed for which are lightness, strength, and rigidity. It is about two-thirds the weight of an ordinary bicycle. The Crypto Works Company

Digitized by Google

show a new form of the "Bantam" having an elongated A-shaped frame, hence called the "Alpha." This is certainly an improvement in appearance on the old form.

With regard to tyres the "make" which seemed to attract the most notice is the Fleuss, a tubeless tyre which for ease of manipulation and durability of material holds a high place. Two of its great advantages are its self-closing property when a puncture is made by an object such as a thorn and the facility with which a larger puncture can be patched until the rider arrives at a place more convenient for a complete repair. The Dunlop Company show their well-known tyres and there are several makes which enter into keen competition with them, such, for instance, as "The Woodstock" (which is arranged for easy attachment and detachment), "The Scottish," "Clipper Reflex," and the Clincher. The self-sealing air-chamber inner tube deserves a word of special notice inasmuch as it is quite possible to stab through and through again and again the tread of the tube without causing any appreciable escape of air. The Glansure tyre, which is made of shark skin, is also worthy of notice and would seem to possess many advantages, but at present it is made in the form of a "stuck-on" tyre and in this respect does not commend itself.

That attention is being paid to the important subject of perineal pressure is illustrated by the multiplicity of patent saddles which are everywhere to be seen. One that is likely to receive notice is the Esmond which has lately been improved and which is still undergoing further improvements. This saddle is so attached that it has a backward and forward motion as well as a side or rocking motion, and practically becomes one with the rider. Pedaling is greatly improved and vibration and concussion are practically absent. Altogether this saddle can be strongly recommended and when the new improvements—namely, a locking device for holding the saddle steady when going up or down hill and a spring under the back of the seat—are added, it will probably be still more appreciated. The "Christy" is another saddle which is used by many with comfort and consists of two pads divided by a metal gutter terminating in a short peak. This latter would be greatly improved if it were padded and it is quite possible that the perineum may be bruised if due care is not taken. Otherwise this form of saddle is a good one. Martin's "Silent Saddle" is of the "peaked" variety, but its construction and form would seem to merit attention. One of the saddles manufactured by Messrs. Webb, Limited, of Birmingham, has a low back-rest running round the posterior portion of the seat. All other things being equal this in some cases should be of advantage.

The "Doolittle" (Singer Cycle Co.) is an ingenious contrivance whereby the machine can be stopped by back pedaling or the speed reduced by the same means. Various forms of brakes are shown, but they require to be inspected in order that their construction may be understood.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6008 births and 4172 deaths were registered during the week ending Dec. 4th. The annual rate of mortality in these towns which had been 18·6 and 20·2 per 1000 in the two preceding weeks declined again last week to 19·8. In London the rate was 20·2 per 1000 while it averaged 19·5 in the thirty-two provincial towns. The lowest rates in these towns were 9·9 in Croydon, 13·1 in Derby, 13·2 in Cardiff, and 14 2 in Salford; the highest rates were 23·8 in Liverpool, 24 6 in Blackburn, 26 2 in Leeds, and 27·9 in Norwich. The 4172 deaths included 541 which were referred to the principal zymotic diseases, against 462 and 552 in the two preceding weeks; of these, 215 resulted from measles, 89 from diphtheria, 77 from whooping-cough, 61 from "fever" (principally enteric), 53 from scarlet fever, and 46 from diarrhœa. No death from any of these diseases was recorded last week in Plymouth; in the other towns they caused the lowest death-rates in Bradford, Preston, and Portsmouth, and the highest rates in Gateshead, Halifax, Burnley, and Blackburn. The greatest mortality from measles occurred in Swansea, Oldham, Huddersfield, Halifax, Gateshead, and Blackburn; from whooping-cough in Bolton and Norwich; and from "fever" in Derby. The mortality from scarlet fever showed no marked excess in any of the large towns. The 89 deaths from diphtheria included 52 in London, 7 in Burnley, 5 in Liverpool, 4 in Cardiff, and 4 in Wolverhampton. No fatal case of small-pox was registered during the week in any of the thirty-three large towns; and no small-pox patients were under treatment in any of the Metropolitan Asylum Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 3811, against 3777, 3792, and 3818 on the three preceding Saturdays; 328 new cases were admitted during the week, against 460, 397, and 375 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London which had been 414 and 471 in the two preceding weeks, declined again last week to 418, but slightly exceeded the corrected average. The causes of 58, or 1·4 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Nottingham, Bradford, Leeds, Newcastle-upon-Tyne and in thirteen other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Leicester, Liverpool, and Salford.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns which had been 18·5 and 19 5 per 1000 in the two preceding weeks further rose to 19·6 during the week ending Dec. 4th, but was 0·2 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13·9 in Aberdeen and 16·1 in Paisley to 27·9 in Greenock and 29·0 in Perth. The 583 deaths in these towns included 22 which were referred to whooping-cough, 15 to measles, 13 to diarrhœa, 9 to scarlet fever, 8 to "fever," and 6 to diphtheria, In all, 73 deaths resulted from these principal zymotic diseases, against 62 and 74 in the two preceding weeks. These 73 deaths were equal to an annual rate of 2·4 per 1000 which was slightly below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough which had been 10 and 23 in the two preceding weeks, were 22 last week, of which 16 occurred in Glasgow and 3 in Greenock. The 15 deaths referred to measles showed an increase of 5 upon the number recorded in the preceding week and included 11 in Glasgow and 3 in Greenock. The fatal cases of scarlet fever which had been 8 and 12 in the two preceding weeks declined again to 9 last week, of which 3 occurred in Glasgow, 3 in Edinburgh, and 2 in Leith. Of the 8 deaths referred to different forms of "fever" 3 were recorded in Greenock and 2 in Paisley. The 6 fatal cases of diphtheria showed a slight further increase upon recent weekly numbers, and included 2 in Glasgow. The deaths from diseases of the respiratory organs in these towns, which had been 145 and 123 in the two preceding weeks, were 125 last week and were 21 below the number in the corresponding period of last year. The causes of 36, or more than 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had increased in the three preceding weeks from 19·8 to 25·4 per 1000, was again 25·4 during the week ending Dec. 4th. During the past nine weeks of the current quarter the death-rate in the city has averaged 23·4 per 1000, the rate during the same period being 18·2 in London and 19·1 in Edinburgh. The 170 deaths registered in Dublin during the week under notice corresponded with the number in the preceding week and included 19 which were referred to the principal zymotic diseases, against 10 and 20 in the two preceding weeks; of these, 12 resulted from different forms of "fever" (principally enteric), 3 from scarlet fever, 2 from diphtheria, 2 from whooping-cough, and not one either from small-pox, measles, or diarrhœa. These 19 deaths were equal to an annual rate of 2·8 per 1000, the zymotic death-rate during the same period being 2 9 in London and 1 8 in Edinburgh. The deaths referred to "fever" which had been 6 and 12 in the two preceding weeks were again 12 last week. The fatal cases of scarlet fever which had been 1 and 3 in the two preceding weeks were again 3 last week. The mortality from diphtheria and from whooping-cough exceeded that recorded in the preceding week. The 170 deaths in Dublin last week included 32 of infants under one year of age and 42 of persons aged upwards of sixty

Digitized by Google

years; the deaths both of infants and of elderly persons exceeded the numbers recorded in the preceding week. Seven inquest cases and 2 deaths from violence were registered; and 69, or more than a third, of the deaths occurred in public institutions. The causes of 9, or more than 5 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-MAJOR ALLAN PERRY retires from the service receiving a gratuity. Surgeon-Major Morris has been posted to the Sind District and Surgeon-Lieutenant-Colonel Le Mottée has been posted to the medical charge of the Station Hospital, Quetta District. Surgeon-Major Lyle has assumed charge of the Station Hospital at Newcastle-upon-Tyne.

INDIA AND THE INDIAN MEDICAL SERVICES.

The services of Surgeon-Colonel Hay (Bombay), Officiating Principal Medical Officer, Bombay and Aden Districts, are placed at the disposal of the Government of Bombay. Surgeon-General G. Bainbridge, lately appointed with the Government of Bombay, in succession to the late Surgeon-Major-General Cook, is the junior of the three Surgeon-Colonels pertaining to the Bombay Medical Establishment. Surgeon-Major Brazier Creagh, who has been on plague duty in Eastern Persia, has returned to Quetta.

NAVAL MEDICAL SERVICE.

Staff Surgeon Thomas Edward Henry Williams has been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet.

VOLUNTEER CORPS.

Artillery: 1st Ayrshire and Galloway: Surgeon-Lieutenant S. A. D. Gillespie, M.B., resigns his commission; Henry Alexander Pattullo, M.B., to be Surgeon-Lieutenant. 2nd Devonshire (Western Division) Royal Artillery: Surgeon-Lieutenant J. P. S. Ward to be Surgeon-Captain. *Royal Engineers: Submarine Miners:* The Clyde Division: Surgeon-Captain J. Whiteforde, M.D., retires under the provisions of paragraph 111 of the Volunteer Regulations, 1896. *Rifle:* 1st Volunteer Battalion the Queen's (Royal West Surrey Regiment): Surgeon-Captain W. Rosser, M..D, resigns his commission. 3rd Volunteer Battalion the Bedfordshire Regiment: Brigade-Surgeon-Lieutenant-Colonel H. F. Holland, M.D., resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the battalion on his retirement, vacating at the same time his appointment as Senior Medical Officer to the Home Counties Volunteer Infantry Brigade. Galloway: Surgeon-Lieutenant J. Cowan, M.B., to be Surgeon-Captain. 3rd Glamorgan: Surgeon-Lieutenant E. Reid to be Surgeon-Captain. 2nd (Angus) Volunteer Battalion the Black Watch (Royal Highlanders): Surgeon-Major R. Grant to be Surgeon-Lieutenant-Colonel. 3rd London: Surgeon-Lieutenant-Colonel W. T. Whitmore resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the corps on his retirement. 1st Dumbartonshire: Thomas John Burton, M.D., to be Surgeon-Lieutenant. 7th (Clackmann and Kinrose) Volunteer Battalion Princess Louise's (Argyll and Sutherland Highlanders): The under-mentioned Surgeon-Captains to be Surgeon-Majors: J. H. Hay, M.D., and D. W. Currie, M.B.

THE SOUDAN EXPEDITION.

There is a great lull in Egyptian affairs at the present time and we are without any reliable news as to the probable course of future military operations. Sir Herbert Kitchener has been to Suakin and Massowah and after paying a visit to Cairo he will return to Berber in command of the Egyptian expeditionary army. In the meantime a force has proceeded to Kassala with the view of taking over that garrison from the Italians, and Egyptian troops will also occupy Massowah. The news about the evacuation of Metemmeh by the Dervishes has not been corroborated, but some of the tribes are deserting from the Dervish army. It seems probable that an advance on Khartoum will be made early next year and that the troops garrisoning Kassala will take part in it. No announcement has yet been made about the employment of British troops with the Egyptian force when the start for Khartoum is made. The Khedive's troops in the field are healthy and everything, as far as the medical service is concerned, is working satisfactorily.

BRIGADE-SURGEON-LIEUTENANT-COLONEL D. D. CUNNINGHAM.

The *Pioneer Mail* of Nov. 19th announces that Brigade-Surgeon-Lieutenant-Colonel D. D. Cunningham, who came to England last April on account of ill-health, will not return to India. This will be a great loss to the service and to the cause of scientific medicine in that country. This officer was Professor of Physiology in the Medical College, Calcutta, and has done a large amount of scientific work of an exceptional, and often of an original, kind in connexion with a variety of subjects—such as cholera, the conditions of ground-soil in relation to temperature, moisture, and disease, the nature of snake poison, &c. He is an expert and admirable microscopist and a good bacteriologist. He has always exhibited the spirit of an independent and impartial observer in scientific research and has won for himself a distinguished position not only in this respect but as a very industrious and highly-cultured man.

A MEDICAL OFFICER'S GALLANTRY.

Brigade-General Ellis, C.B., in his despatch relative to the action near Shabkadr on the Indian frontier refers to the services of Surgeon-Captain T. H. Goodwyn, Army Medical Staff, in eulogistic terms. The general brings to very special notice the gallantry of this officer, the only medical officer with the force. "He was attending to the wounded wherever the fire was hottest and showed great devotion to his duty. He was himself knocked out of time by a stone or spent bullet but refused to leave his work."

ALUMINIUM COOKING UTENSILS FOR FIELD SERVICE.

The French in Madagascar have been using aluminium for cooking utensils with, it is reported, satisfactory results. In lightness, cleanliness, and non-liability to rust aluminium has great advantages, but it has one very serious drawback for field service in that utensils made of this metal cannot be repaired by any process of soldering.

THE OUTBREAK OF SCARLET FEVER AT THE GUARDS' DEPÔT, CATERHAM.

In order to check the spread of scarlet fever at Caterham an isolation camp has been formed for the occupation of the men of the depôt not required for duty in barracks.

Notification has been received that the s.s. *Dilwarra* left India with 309 invalids for Netley. She is due to arrive at Southampton at the end of the present week.

"ON THE CLIMATIC TREATMENT OF PHTHISIS."

To the Editors of THE LANCET.

SIRS,—The communication of Dr. Walters on the above subject in THE LANCET of Nov. 20th will have been read with especial interest by those who are occupying themselves with the question, How can phthisis be more adequately treated in this country than it is at present? The continental sanatoria for the hygienic treatment of phthisis have become an established success, and Dr. Walters argues that "the essential features of a successful health-resort for the cure of phthisis" obtain in parts of our own country. During the last two and a half years I have put this to the test in a convalescent home at Cromer. A suitable shelter has been provided and twenty-four phthisical patients have undergone the "open-air" treatment there for periods varying from one to fourteen months. The results obtained—especially those of the winter months—have been surprisingly encouraging. As I hope to publish an account of these cases shortly I will only say now that three-fourths of them manifested marked improvement which has been maintained till now.

I am, Sirs, yours faithfully,

F. W. BURTON-FANNING, M.D. Cantab., M.R.C.P. Lond.

Norwich, Dec. 6th, 1897

CRIPPLED CHILDREN'S CHRISTMAS.

To the Editors of THE LANCET.

SIRS,—By a vote of the Court of Common Council to-day the Corporation of the City of London has for the fourth time granted the use of the Guildhall for the Christmas entertainment to ragged school children which it has been my privilege annually to promote. The guests are drawn from all of the poorest parts of the metropolis. I am sure that the sight of their radiant faces at the well-spread board under the eye of those genial giants—Gog and Magog—must have repaid the kind-hearted donors of this joyful feast. I have every confidence that the generous public will once more assist as liberally as heretofore, but this year I ask for your coöperation to make a special and wider appeal.

There are over 5000 little crippled children passing a monotonous existence in crowded courts and alleys in this great city. Many of them are stretched on beds of suffering and are prisoners from year's end to year's end. Others are quite unable to participate in the pleasures offered to the more robust. Realising how sad was the lot of these afflicted little ones last year the surplus of the funds entrusted to me for the children's banquet at the Guildhall was spent in providing 100 Christmas hampers for crippled children. There was not the smallest difficulty in distributing them to the most deserving cases, for every cripple is registered and visited systematically by the Ragged School Union. But in making the selections it gave great pain to be obliged to refuse four out of every five applicants. Why should not all the 5000 homes be brightened and made happy for one day at least in the year?

It rests simply with sympathetic people to provide the means. The cripples' Christmas hamper may be large or small according to the measure of support I may receive. Last year it contained a 2 lb. meat pie, a plum-pudding, a substantial cake, a packet of tea, and a parcel of sweets; and judging from the pathetic letters of thanks these unaccustomed dainties—the mere elements of Christmas fare—gave untold satisfaction. That is why I want to disappoint no child-cripple this year out of the 5000 and that is the reason why I would earnestly ask for contributions, large or small, to be sent to the Little Cripples' Christmas Fund, care of Alderman Treloar, Ludgate-hill, E.C.

I am, Sirs, your obedient servant,

Ludgate-hill, Nov. 18th. W. P. TRELOAR.

"DR. RENTOUL'S CLAIM FOR FEES FROM THE MEDICAL COUNCIL."

To the Editors of THE LANCET.

SIRS,—In your issue of Dec. 4th, under your report of the November session of the Medical Council, reference is made to a claim made by me for a fee of £10 10*s.* 0*d.* from the Medical Council. My claim rests upon the following Standing Order of the Medical Council:—Section XI. 4: "Each member of the General Council who *resides* more than two hundred miles from London shall receive five guineas for the day of his coming and five guineas for the day of his return." In so far as I can find out, the Treasurers of the Medical Council (Sir D. Duckworth and Mr. Bryant) object to pay me the 10 guineas for the three following reasons:—

1st. That Mr. M. Banks, when on the Medical Council, did not receive any payment under the above Rule. From what I have learned, I believe Dr. Banks did not know of this Rule. Had he known, I feel fairly certain he would have claimed. But I have stated that I refuse absolutely to be bound by what *one* member of the Medical Council has done. The above rule was made—not by *one* member of the Medical Council, but by the majority of the Council, and in 1859. Let me project this excuse for non-payment a little further so as to see how ludicrously ridiculous it is. Suppose Dr. Banks had refused to take any payment whatsoever. Such an action of his could, according to the Treasurers, be used against me, or any other member, just as the above has been! Either the above rule is, or is not in force. If it be still in force, let it be honestly put into force. If not, let it be struck out.

2nd. Sir D. Duckworth and Mr. Bryant contend that the above Rule does not take in the distance from my *residence* to the Medical Council office. I contend that it does. The word "resides" is expressly and pointedly used in the above Rule. Do they contend that I "reside" at the railway station! The distance from my residence to the Medical Council is 204¼ miles. I contend that under the term "resides" is included the *total distance* travelled by a member attending a meeting of the Medical Council. It can not include *railway* travelling only. Else how could the Irish Representatives, when travelling by boat, be justly dealt with. Again, supposing a Member has to drive 5 to 10 miles, is this distance not to be included when making up the total 200 miles?

3rd. Sir D. Duckworth and Mr. Bryant wrongly calculate the distance to London upon the charges made by the Railway companies from their third class parliamentary fare. No method of calculating is more absurd. In my letter of July 13th, '97, I particularly pointed out that the railway fare charged was *not* based upon *the distance*, but was due to the prices charged for tickets *by the competing railway companies*. In his letter to me of June 16th he says—"the Parliamentary fare to Liverpool, 16*s.* 6*d.*, is calculated on the basis of the distance being 198 miles." This is a very gross and grave inaccuracy, and especially so when made by Teasurers of the funds of the Council. There are three chief railway lines from Liverpool to London: the L. & N. Western; the Midland; and the Great Western. The distance *from station to station* (Liverpool to London), by the L. & N. W. is 201 miles; by the Midland, over 218 miles; and by the Gt. Western 228 miles. By Section 6 of the Cheap Trains Act, 1844, it is enacted that the Parliamentary fare shall not 'exceed' one penny for each mile. But, be it noted, this act does not say the railway companies shall not charge *under* one penny per mile. Evidently Sir D. Duckworth and Mr. Bryant fancy the railway companies charge just as high a price as they legally can. But this is not so. Competition among railway companies steps in as among other affairs of life. If the railway companies charged up to their legal rates, the Gt. Western with its 228 miles, at 1*d.* per mile, would charge 17*s.* 8*d.* (it actually, with the *longest* distance of the three, charges 16*s.* 2½*d.*: the Midland, with its over 218 miles could charge 18*s.* 0½*d.* (it actually charges 16*s.* 6*d.*): while the L. & N. Western with its 201 miles could charge 16*s.* 9*d.* (it actually charges 16*s.* 6*d.*). Therefore, by the shortest distance from station to station (upon the chief objection of Sir D. Duckworth and Mr. Bryant) is 201 miles. This being so, and taking it that the above Rule refers only to the distance from station to station I can honestly claim the above fee of £10 10*s.*

All the above facts were laid by me before Sir D. Duckworth and Mr. Bryant in my letters of June 14th and July 13th, '97. Let me just add, I believe this pettifogging action of these two gentlemen would not have taken place had I not, at the last May session of the Medical Council, stated, when the subject of Medical Aid Associations was before the Council, that if the Council was to act honestly in this matter, it must wash its own hands first, as at least one Member of the Council was connected with a London hospital (Guy's) which was to all practical purposes a large medical aid association at which persons, by paying threepence per week, or sixpence per fortnight, could obtain out-patient medical and surgical treatment and medicines; the medical officers being specially paid about £100 per annum each for such services; and where beds for in-patients were advertised at from 21*s.* to 63*s.* per week. If this statement is false, then I publicly challenge the members of the Medical Council connected with this "hospital" (or medical aid association) to deny it.

There are two other statements made by Sir D. Duckworth and reported to which I wish to refer. He stated before the Council that I asked him if I was to be paid for my wife's presence in London. I can only answer this gross impertinence by publicly stating that the person who said it is a gross perjurer of the truth. Is it likely that I would make such a claim, or if I thought I could make it would I not first have read the rules of the Council or asked the Registrar privately? Evidently the mantle of knighthood sometimes covers those who are not above using the grossest slander. I have been "blackballed" by the members of the Liverpool Medical Institute for membership on account of the action I have taken upon the question of abuse of medical charities. This I do not much mind. But if Sir D. Duckworth insists in dragging in others closely related to me I shall take a very sharp method of trying to teach him how to act as a gentleman. His other gross y untrue statement is "that Dr. Rentoul had got the Chief Constable of Liverpool

Digitized by Google

to measure the distance from his residence to the railway station." I am yours,

Liverpool, Dec. 5th, 1897. ROBERT R. RENTOUL.

*** Having reported the statements to which Dr. Rentoul takes exception we publish his letter at the same time deprecating the unnecessary violence of his language.—ED. L.

THE MEDICAL STAFF OF THE SEAMEN'S HOSPITAL SOCIETY.

To the Editors of THE LANCET.

SIRS,—The attention of my committee has been drawn to a letter that appeared in your paper on the subject of the titles of the honorary medical staff of this society, and I am directed to send you the following copy of a minute which was passed on April 10th, 1896:—

"That in future the title of all honorary medical officers appointed to the branch hospital be Visiting Physician or Surgeon (as the case may be) of the Seamen's Hospital attached to the Branch Hospital; and that in future appointments to the Hospital at Greenwich the title of Visiting Physician or Surgeon (as the case may be) of the Seamen's Hospital attached to the Dreadnought Hospital."

I am, Sirs, yours faithfully,

Greenwich, Dec. 8th, 1897. P. MICHELLI, Secretary.

*** The letter to which our correspondent refers is probably one which appeared in our issue of Oct. 30th, 1897, under the heading "Beri-beri and Erroneous Diagnoses."—ED. L.

"TEMPORA MUTANTUR, NOS ET MUTAMUR IN ILLIS."

To the Editors of THE LANCET.

SIRS,—I have been in practice for thirty-seven years and have brought up a large family. It has always been my endeavour to keep up the dignity of the profession though of late it has been increasingly difficult to do so. The authorities, both medical and legal, have deprived me or have allowed me to be deprived of many rights while burdens have been imposed which lower my income and increase my expenditure. Having paid a premium myself I had reason to suppose that I might some day take pupils and recover my outlay, but that privilege is denied me. For copy certificates of the cause of death I used to receive payments ranging from 1*s.* or 2*s.* 6*d.* in the case of poor people to 1 guinea or 2 guineas in the case of large insurances. Now the registrar not only copies my certificate but takes the fee. At considerable personal inconvenience and expense I acquired proficiency as an accoucheur and had a fair proportion of midwifery cases to attend, but now certificated nurses are permitted to attend them and they take the fees so that part of my income is lost. All fractures and other injuries in the streets are at once attended to by the active and intelligent constable, who would lose caste if he called in proper professional assistance, so I do not even get the chance of earning the wretched 3*s.* 6*d.* which police regulations allow.

As I cannot have a pupil I am driven to choose between a qualified assistant, who expects me to pay him a salary while I teach him his practical work at my own expense, and an unqualified assistant, with the risk of being treated as a criminal if anything should go wrong with any patient whom he has once looked at. As if impoverishing causes from outside the profession were not sufficiently numerous some of my neighbours have allied themselves with medical aid societies and by their agents systematically call on my patients and press them to join the "doctor's club" as they call it and thus more of my income is diverted from its proper course. So serious is the effect of these combined causes that during the last two years my income is reduced by £190. This has thrown me into a position of great difficulty and distress. My youngest son, who is commencing his third winter, has received notice that unless his fees amounting to £30 are paid forthwith he will be excluded from lectures. He is an ardent and eager student and it will be heartbreaking work if I have to keep him at home, but I do not know how to get the money. I have already paid £80 to the hospital besides examination fees. What can I do? Is there any fund available in such a case? Perhaps some of your readers will kindly throw out a suggestion.

I am, Sirs, yours faithfully,

Dec. 6th, 1897. PATERFAMILIAS.

THE NOTIFICATION OF PUERPERAL FEVER.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Nov. 27th[1] it is stated that a medical officer of health is dissatisfied with the manner in which the notification of puerperal fever is carried out in his district. If other medical men have to contend with what I have had to twice lately I wonder notification occurs at all. A year ago I notified a case of puerperal fever to the medical officer of health of an adjoining parish with the result that he sent a loud-voiced inspector who in the passage of a four-roomed cottage talked about "infection, disinfectants, and death," the patient of course hearing it all and being much upset. A few days since it became my intense misfortune to notify a case to another medical officer of health and this is what happened. The sanitary inspector called, in not the most gentle way, then a few days later the medical officer of health who, without having communicated with me, cross-questions the nurse (also in a four-roomed cottage with the patient upstairs with a temperature of 104° F.) as to whether instruments were used, if used properly (the nurse had to admit she had never before seen them used), if the instruments were boiled, if any disinfectants were used by me (the nurse was so flurried at the sight of instruments she could not say), if there was any difficulty in getting the placenta away, and if I douched afterwards, &c., &c. As the husband said to me, "All this questioning of the nurse would make it appear as if you had not done your duty."

All this is not pleasant to either patient, medical man, or the household at a time when there is so much anxiety to bear. Could not medical officers of health exercise a little more tact? Of course inquiry must be made and should be courted by all. Surely a quiet note to the nurse from the medical officer of health asking her to see him at his office on a nursing matter (there to be questioned as to whether the forceps were put on properly, &c.), and then if necessary a visit to the house and patient as a friend of the attending practitioner, ought to be sufficient without paying surprise visits. I cannot help thinking that in such an illness as puerperal fever no interference should be allowed with the house or patient until the illness is well over. Why should not a medical man exclude the authorities in the same way that he does the friends? I have no wish to draw attention to any particular officials but only to point out a very likely reason for risking a £2 penalty and costs.

I am, Sirs, yours faithfully,

Nov. 30th, 1897. NOTIFICATION.

PLAGUE IN INDIA: ITS SPREAD AND ITS PREVENTION.

(FROM A CORRESPONDENT.)

"PROXIMUS ARDET UCALEGON."

RECENT events in India have shown how little regard is paid to the dictates of science until these have been confirmed and emphasised by a terrible experience. There is therefore all the more reason to hope that this experience will not be lost and that its lessons will be borne in mind, in view of the facts (1) that plague is undoubtedly showing a tendency to spread in India, and (2) that when the proper measures are taken in time there is no disease the spread of which can be so certainly checked and finally arrested. Although we do not know all about the modes of spread of plague we now know enough of the subject to enable us to deal confidently with local outbreaks, where the men, the means, and the money are forthcoming—and this is not merely a forecast, but a result achieved in more than one instance of local outbreaks in the present Indian epidemic. Of these, Hurdwar in the North-West Provinces, and Shikarpur, Jacobabad, and Tatta in Sind, are examples, while there is no doubt that the early extinction of the disease in Karachi was due to the comparatively prompt measures taken there. Plague, from its public health aspect,

[1] Report of the Medical Officer of Health of Oldham, reviewed in THE LANCET of Nov. 27th, p. 1411.

Digitized by Google

comes, then, to be considered, firstly, as to its modes of propagation and, secondly, as to the prevention of its spread.

THE PROPAGATION OF PLAGUE.

Although we do not know all, or nearly all, that is to be known of the bacillus of plague we have yet become acquainted (through the labours of bacteriologists on the one hand and through the experiences of those who have intelligently studied the history of the disease as it has appeared to them under various local conditions on the other) with a sufficient number of unassailable facts upon which to formulate rules for practical application in cases of plague whether imported or local. Thus we know that the individual bacillus is short-lived and may be easily destroyed, but is capable of enormous multiplication in a short time under favourable conditions; that no spore has ever been found and that it may be hoped that such a spore does not exist. We also know that certain animals are obnoxious to infection and that most, if not all, of them can be rendered immune for a longer or shorter time by inoculation with attenuated virus. The bacillus has been found to thrive most in floors of houses whose inmates have been infected, and it seems to the writer to be proved by experience in various local epidemics in India that the disease in its epidemic form is essentially one of floors of houses rather than of humanity, though the medium of importation in the first instance is generally either an infected person or (much less frequently) infected clothing.

The bacillus has been found in most of the organs of those dead from the disease. Its presence in the living blood is by no means satisfactorily made out; but it is held by some who regard the disease as invariably conveyed by inoculation that the bacillus may be found in lymph-channels, glands, and blood, but that its presence in the blood is necessarily of fatal import. Apart from the inherent improbabilities of the theory that every infected person has been inoculated through an accidental fissure or abrasion this view is, the writer thinks, negatived by the fact that incision of the gland at an early stage, which involves giving free access of the gland bacilli to the blood stream, was followed by recovery in the majority of cases thus treated in the Karachi plague hospital.

The facts observed in India lead to the belief that the invasion by the bacillus comes about in many ways and that inoculation is one of the least frequent of these, while the modes of invasion by the lungs and stomach are probably the most common. The writer is not aware of any experiments made as to the presence of the bacilli in the air of infected rooms, but the facts that the disease chiefly attacks those who live or sleep in an infected quarter and that the bacilli, while swarming in the floor surface, are found with difficulty or not at all on the walls of an infected room, tend to show that contact with the poison must be intimate and prolonged to ensure infection. Were this not so the work of a plague superintendent would be much more dangerous than it has actually proved to be. The presence of the bacillus in the various excretions furnishes an obvious explanation of house floors in native houses becoming infected and the question of the spread of the disease to the neighbouring houses comes to be considered. The view that this occurs by human intercommunication was naturally that which was first entertained, but reflection, on further experience, tends to show that though this may be the method of spread in some cases it does not satisfactorily account for the regular advance of the disease house by house and street by street from its original focus which is so often seen and some other cause for this phenomenon came to be sought for.

It was noticed, not once but many times, that in the case of a town which was itself free from infection but in very close connexion with an infected city (as at Hyderabad about 100 miles from Karachi) cases of plague first occurred in persons lately arrived and that it very often happened that several cases of the kind occurred at longer or shorter intervals before the first local case was reported in the person of an inhabitant of the hitherto uninfected town and that simultaneously with the first appearance of the local epidemic rats were found to be dying in numbers from plague in the dwelling of the original imported case, the local case, or in both. Of course, many theories as to the method in which this occurred may be, and have been, formulated, the most obvious being that of the rats having infected the floors of the next dwelling and thus given rise to a local outbreak. Thus, a rat poisoned by excreta from an imported case travels to the next or to a neighbouring house and infects the floors there. There are plainly many arguments to be raised against this simple explanation as it does not "fill the bill" in every respect unless we suppose rats to have been non-existent in the house or houses in which the first imported cases developed. Yet the fact remains that the appearance of local plague and of rats dead from the disease, as proved by bacteriological examination after death, were in very many cases simultaneous and a consideration of the fact that the floors are the chief breeding places of the bacillus renders the explanation a probable one. In well-ordered hospitals where the floors were constantly sluiced with disinfectants the danger to the medical officers, nurses, and hospital attendants was practically *nil*—as seen in Karachi—whereas in other instances where these measures were neglected the result was invariably the spread of the disease to those engaged in tending the sick. Of course, accidents will happen and even in the best regulated hospital a case of plague may occur among the medical staff or attendants, but this is rare, and the writer has always regarded the occurrence of a number of cases amongst the staff of a plague hospital as an indication of imperfect management, especially as to the use of disinfectants, and this has invariably been found on inquiry to have been the case.

THE PREVENTION OF THE SPREAD OF PLAGUE.

The principles underlying this are rational and as already stated have been proved capable of being put into effective operation. These principles are to secure early detection of cases of plague and to arrange for isolation of the sick, segregation of the inhabitants of infected quarters, and disinfection of all such quarters and of all bedding, clothing, &c., which may harbour the microbe.

In India the early detection of cases was effected in various ways by search parties, civil or military, under the direction of a medical officer, by offering small rewards for information, and by private inquiry, and although at first some difficulty was experienced it was found that when the nature of the disease was understood such information was often voluntarily given by persons living near the infected quarters. In Bombay the spread of the disease may fairly be attributed to two causes—firstly, the non-recognition of its nature when it first appeared in a poor and dirty portion of the city where the people do not as a rule call in the aid of European physicians; and secondly, the reluctance on the part of the local government to institute measures which would interfere to some extent with the prejudices of the ignorant native population.

It was held by some in local authority that the plague must run its course and although information to the contrary was promptly forthcoming from the professional advisers of the Government the mistake, which doubtless those responsible have been the first to acknowledge and regret, was made and a policy of *laisser faire* was inaugurated and maintained until too late. Fortunately better counsels have now prevailed and the plague, whether in Bombay or elsewhere, has been dealt with more or less promptly and *pari passu* more or less efficiently. In Karachi, where plague was not reported until December, 1896, similar indecision at first marked such action as was taken, but the value of the measures advocated by medical authorities both in India and at home was soon appreciated by the chief administrator in Sind, and these measures when taken were very thoroughly given effect to, and this without giving rise to any serious discontent among the Mussulman inhabitants—a virile race who contrasted strongly with their Hindu compatriots both in Sind and the Deccan—while absolutely no outrage of any kind occurred.

These facts are strong presumptive proof that the agitation against plague measures—resulting in the deplorable and dastardly outrage which marked the night of Her Majesty's Jubilee in Poona—was an artificial agitation, nursed and fomented by seditious persons with plague measures as a watchword for want of a better pretext. The idea that the murders of Messrs. Rand and Ayerst had any closer connexion than this with plague measures is not entertained by thinking people in India.

To return to these plagues measures. The sick are isolated either in camps or in existing buildings, and in the Presidency proper the latter are a necessity during the rains. In Sind the Government school buildings were frequently utilised for the purpose.

The arrangements for the treatment of the sick and the

Digitized by Google

protection of the healthy in hospital are now well understood by a large number of medical officers in India who have had charge of such institutions. As regards segregation the ideal aimed at in the first instance and carried out in great perfection and detail at Sukkur, in Upper Sind, was to provide accommodation separately: (1) for the sick; (2) a segregation camp proper for the inmates of infected houses; (3) a health camp for the probably uninfected inmates of neighbouring houses; and (4) a detention and observation camp for persons going from, or coming to, the infected city, each with a separate staff. More extended experience has, however, inclined the writer to believe that this multiplication of camps is unnecessary, and although the arrangements at Sukkur left little to be desired in the matter of efficiency this was only achieved with a large staff and at great expense.

At Tatta, in the Karachi Collectorate, a different and less elaborate method was carried out under the writer's direction, a plague hospital was established, and two camps were erected close together so as to admit of their being administered by a single superintendent. These camps were only divided by a roadway and into one of them were sent all persons from infected quarters, while the other—a larger settlement—was used both as a hospital and a detention camp. It is found that when the number of cases in a town increases there is an exodus of the people, and that as soon as the epidemic shows signs of abating there is a corresponding return of the exiles, so that the numbers of each class are complementary and the amount of camp accommodation required for both is practically constant. Hence this large camp was not only used as a health camp but was occupied for eight days by all persons either leaving the infected town or returning thereto, while the opportunity was taken to disinfect by boiling in large caldrons the clothing and effects of all in the camp both on admission and discharge. This method was found to be free from all danger of spreading the plague in the camp; and it is now an established fact that where camps are well looked after, disinfection being thorough and destruction of huts in which cases occur being prompt, there is no danger of a camp epidemic. The disinfectant now almost exclusively used is a 1 in 1000 perchloride of mercury acid solution, and it has proved so satisfactory and so cheap that it is inadvisable to seek further and possibly fare worse.

A somewhat extended experience of plague camps of various kinds has impressed upon the writer the feasibility of still further simplifying the work by the establishment (1) of a hospital and (2) of a single large camp for use as segregation, health, and detention camp in one, as it is found by experience that camp epidemics do not occur in segregation, any more than in health, camps when proper care is taken. The arrangements for sanitation, police, water- and food-supply, disinfection, registration of admissions and discharges, and medical inspection of all inmates twice daily are, of course, much more readily and economically carried out in a single large camp than in a number of small ones, and these arrangements are now well understood by many officers, both lay and medical, in India. The chief difficulties in carrying out plague measures are encountered (1) during the monsoon, when camps are uninhabitable; (2) in large cities; and (3) in small villages. But all these may be, and in many instances have been, overcome. During the monsoon if no camp formation is possible vacant quarters are often available outside the town, and if not it still seems possible to empty an outlying quarter of the town itself, and use it for the purpose, while if thought necessary the fine weather may be utilised for making existing camps watertight or erecting new ones.

In large cities the magnitude of the task forms its chief difficulty, especially if the epidemic has been allowed to make much headway before any measures are taken. The results achieved in Bombay city have proved how much, even in this case, may be done. In the case of small villages, Sind experience goes to prove that the disease has a tendency to die out, probably from exposure to wind and sun, and this was found to be the case not only in Upper Sind but in the villages in the Karachi district where the air is comparatively moist. The chief danger lies in the conveyance of plague from village to village till it meets with a large town or city, and this can be to a great extent prevented by the promulgation from the office of the chief civil authority of a notice warning the inhabitants of healthy villages against admitting persons from a known infected town into their community. Such a warning is doubtless regarded by many of the villagers as an order and it has undoubtedly the effect of strengthening the hands of the village Panchayet in the matter. At Daharki, on the Sind-Punjab frontier, the writer observed an instance of self segregation and exclusion of infected persons from surrounding villages initiated by the people themselves and followed by the best possible results.

In the present state of our knowledge as to the part played by the rat in the spread of plague it should be the object of special attention and its destruction is more safely and surely effected by trapping and shooting than by the use of poison.

Locally the above represents all, or nearly all, that can be done and when done thoroughly the results are always valuable, but in view of the facts that counsels of perfection are much more easily given than followed and that railway facilities are as likely to be utilised by the bacillus as by its possible host, it becomes necessary to form a second line of defence for uninfected districts or provinces at a distance from the focus of infection. This is best done by establishing railway detention camps and disinfecting stations on the line of rail (preferably at a junction) beyond the known infected area where passengers and kit are derailed and disinfected, the former by an antiseptic bath and the latter by steam at high pressure. The arrangements as carried out at Sukkur, Khanpur, and Shikarpur for the protection of Baluchistan and the Punjab were simple and proved effective. It is understood that a scheme of a similar nature for the protection of Madras, Central India, the Central and North-West Provinces, and Rajputana submitted by the writer to the Bombay Government has now been put in operation on the various lines of rail passing through, and beyond, the infected areas in the Bombay Presidency.

In conclusion the following instances (1) of the value of floor disinfection and the danger of its neglect, and (2) of the value of segregation may be given.

In the Karachi plague hospital where the floors were constantly soaked with disinfectant not a single case of plague occurred among the attendants during six months if we except the case of a lady nurse who was attacked but recovered. At Karad, in the Satara District, on the other hand, where floor disinfection during the first two months of the epidemic there was little more than a name, the hospital assistant died from plague contracted in hospital, the child of another hospital assistant was attacked but recovered, and of six ward attendants two died from the disease, while it is believed that since the disinfection of ward floors has become a matter of daily routine no further cases have occurred in the hospital staff there. The danger of house destruction or cleaning without previous disinfection was tragically exemplified at Sukkur in the beginning of the terrible epidemic there in March, April, and May last, no fewer than five (and possibly more) of a gang of twenty coolies engaged in pulling down a large tikhana (temple) without previous disinfection having died from the disease within a week. The pulling down of houses, though at first resorted to somewhat freely, is in most cases unnecessary and is always a costly business. When houses are obviously unfit for habitation the presence in them of plague may form a plausible pretext for the process; but in no case should this be done without previous thorough disinfection of the house, the floorings receiving especial attention. Coolies engaged in cleaning out plague houses always receive instructions to spray thoroughly the floor and walls of each room with disinfectant before entering it; and it is to be feared that most of the cases of plague which occurred among these coolies were due to their ignorant disregard of the instructions given them. The value of segregation was markedly shown on many occasions—the most notable that came under the writer's observation having been at Sukkur, where the survivors of an epidemic which had its centre in a poor outlying quarter, known as Gharibabad, were, to the number of 601 persons, moved simultaneously into a fully equipped camp about a mile distant. These 601 were the survivors of about 1000, the remainder of whom had been seized with plague at the rate of 25 per diem *in the preceding 16 days*. Of these one individual developed symptoms of the disease within twenty-four hours of his arrival in camp, after which not a single case appeared among the remaining 600. Another instance of successful segregation on a smaller scale occurred at Igatpuri on the Great Indian

Digitized by Google

Peninsular Railway, where the inmates of a block of buildings, railway porters and their families, were found to be suffering from plague. In the absence of other accommodation the unaffected were placed in railway wagons which were duly disinfected and no more cases occurred among them.

The occurrence of cases of plague amongst those freshly segregated is, of course, to be expected, especially in the first four or five days after admission to camp, but, as already remarked, this need cause no uneasiness if proper use is made of disinfectants, while the very occurrence of these cases is a proof that the necessity for segregation existed. In one instance of a local outbreak during the rains no attempt at segregation was made, while disinfection was very thoroughly done, and here it was found necessary to repeat the process of disinfection many times—once as often as seven times—in the same houses owing to their re-infection by persons who were left there for want of segregation accommodation while in the incubation stage of the disease. It is stated in the press that the official report upon plague is completed and is about to be sent home to the Secretary of State for India. It is to be hoped that when it is published this high officer will see fit to direct that a plague code for guidance in future epidemics, should such unfortunately occur, be drawn up by competent officers and published under the authority of the Government of India.

THE EPIDEMIC OF TYPHOID FEVER AT BELFAST.

(FROM OUR SPECIAL COMMISSIONER.)

To understand the present singular and distressful condition of affairs at Belfast it is first necessary to realise the wonderful rapidity with which the town has grown. In one sense the measure of its prosperity is also the measure of its distress. Not that this need necessarily have ensued. Indeed, the very contrary should have been the case. It would be necessary to go to America to find similar examples of rapid development. The number of new houses erected every year is a clear indication of the growth of Belfast. This has fluctuated from 840 in 1862 to 2538 in 1895 In 1861 there were 18 375 buildings in the city. The number rose to 31,645 in 1871, to 43 790 in 1881, and to 57,540 in 1891. Prior to 1878 there were 796 new streets and in 1891 there were 1618 new streets, all laid out, paved and sewered at the cost of the owners of the property; and this has been done since the passing of the Belfast Improvement Act of 1865. The population of Belfast was set down at 48,224 in 1831. It reached 100,301 in 1851, 174,412 in 1871, and 255 235 in 1891. To-day it is supposed to exceed 300,000. According to the Registrar-General's estimate the population for the year 1896 should have been 277 354. This is calculated on the rate of increase during the decade 1881 to 1891. The number of Parliamentary and municipal voters, together with the number of new houses recently built, indicates that the increase of population is more rapid than that which is shown by the last decade. According to the Registrar-General's return the birth-rate for 1896 would be 37 4 per 1000 and the death-rate 25·1. But according to local calculations, which estimate the population at over 300,000, the birth-rate would be 34 5 and the death-rate 23·1 per 1000; while if estimated according to the census population of 1891 then the death-rate for 1896 would amount to 27·2. It is not altogether easy to decide which of these three estimates is nearest to the truth; but in any case the fact remains that even if the most favourable version be adopted the death-rate is still much too high. Then according to the lowest estimate the zymotic death-rate was 3 3, and according to the highest computation 3·9 per 1000. Of the sixteen principal urban districts of Ireland that of Londonderry alone exceeds Belfast in its zymotic death-rate. The average zymotic death-rates for these sixteen towns was equal to 1·5 per 1000, so that Belfast stands out in very unpleasant contrast with the other urban districts of Ireland.

It is considered that the population of Belfast increases at the rate of about 10,000 per annum. During the last four years more than 2500 new houses have been erected each year and there were in July, 1896, the last figures I have been able to procure, 62 207 houses. Of this number 27,463 had privies and 22,746 had no back passages, so that the refuse has to be carried through the houses into the street. This refuse in 19,095 cases included night-soil, for of the houses without back passages only 3651 had water-closets. When the night-soil has been carried through the inhabited rooms of a house that house becomes temporarily unfit for human occupation and it would not be too much to insist that its inhabitants should go and live elsewhere for a day or two. Such a barbarous state of affairs, it will be thought, must have arisen in olden days when the country was plunged in ignorance and knew nothing about sanitation. This, however, is not the case. Belfast is a modern town. These abominations are of recent creation and the local authorities were much to blame. It was their duty to enforce sanitary laws, whereas it has been their practice to neglect such enactments. Not only has the spirit of the law been overlooked but its very text has been defied by the authorities themselves. This is so strong a statement that I would scarcely venture to make it on my own account and responsibility; but I hold in my hand a document which the corporation itself has printed and issued and it is on this document as well as on my own personal observations that I base this accusation.

A special committee was appointed by the corporation on Aug. 1st, 1896, to "consider and report on the high death-rate of Belfast and the unsatisfactory condition of its public health generally." This committee was composed of seven councillors and two aldermen. The report commences with the damaging acknowledgment that the sanitary authority of Belfast is the Council itself. Under Section 5 of the Public Health Act (1878) the council is authorised to appoint a committee to discharge the duties of the sanitary authority and it is called the Public Health Committee. Though the Council as a whole is legally liable the practical work and responsibility rests therefore with the Public Health Committee. But to do its work the committee must have an efficient staff and at that time there was but one clerk for the whole department and but one inspector in charge of 2715 workshops and factories. Of these about 500 are factories and since 1891 the responsibility for cleansing, overcrowding, ventilating, and lime-washing of workshops rests with the sanitary authority and not with the Government factory inspector. With regard to the population at large there was only one sanitary inspector for every 30 000 inhabitants. Consequently the supervision exercised was qualified as of "the most superficial character" by the writers of the report. The Special Committee then proceed to deal with the 19,000 houses which have no water-closets and no back passages and they state that this "is a state of things which exists in no other town in the three kingdoms to anything like the same extent. The privy and ashpit system no doubt exists elsewhere, but in no other place except Belfast is this system aggravated by the absence of back passages and the consequent necessity of removing the excreta and every other form of refuse through the dwelling rooms of the family. Nor have all these houses been built long years by when sanitary science was in its infancy. Large numbers have been built within the past twenty years and built after the full gravity of the situation was apparent to, and recognised by, the corporation and by Parliament." Nevertheless, the report relates that so recently as 1895 eight water-closet houses were allowed to be built without back passages. The fact that these houses had water-closets somewhat mitigates the evil, but the contents of the ashpits would have to be carried through the dwelling rooms. These ashpits, which in 19,000 houses are also privies, are generally unpaved and the walls are rotten and uncemented; they are uncovered and during wet weather are full of liquid filth. These ashpits and privies have been condemned over and over again by Dr. Whitaker, the medical officer of health of Belfast. To quote his own words, "The ashpit is at the wall of the dwelling house and the noxious damp creeps up the wall of the small room behind the kitchen in which occasionally a patient suffering from bronchitis or phthisis is lying on a wretched bed stretched on a tiled or earthen floor." But the complaints of the medical officer "have been merely ordered to be printed and then allowed to be forgotten."

In support of the assertion I ventured to make that the local authority had failed to carry out the law I must quote in full from pages 9 and 10 of the report issued by the

Digitized by Google

Special Committee appointed by the Town Council the following passages:—

"There is no doubt that the Improvement Committee is primarily to blame in this matter. They have permitted these houses to be built. They have allowed the ashpits of both water-closet and non-water-closet houses to be constructed contrary to law. Section 44 of the 1878 Act requires *every* ashpit to be furnished with 'proper doors and coverings.' Any person contravening this statute is liable to a penalty of £20. Yet notwithstanding this penal statute owners have been allowed since 1878 and in many cases after 1890 to erect houses with ashpits unprovided with either doors or coverings. With regard to ashpits in the thousands of non-water-closet houses of the city no attempt has been made to have them 'provided with proper doors and coverings,' though the Act required this to be done and the executive sanitary officer told us that he nearly got a vote of censure from his committee for trying to get the Act of Parliament obeyed. After considering all these circumstances we can come to no other conclusion than that the Improvement Committee has practically allowed this important provision of the Public Health Act requiring all ashpits to be covered to remain a dead letter and that the Public Health Committee has taken no means whatsoever to have the evil effects of this neglect remedied."

The next legal point comes under Section 25 of the Public Health Amendment Act, which runs as follows: "It shall not be lawful to erect a new building on any ground impregnated with fæcal, animal, or vegetable matter or upon which any such matter has been deposited unless and until such matter shall have been properly removed by excavation or otherwise or shall have been rendered or become innocuous." Up to the year 1892 there was no systematic removal of refuse garbage. Some persons emptied their own ashpits and privies into the nearest plot of vacant ground. Others sold their contents to farmers. The worst feature is the fact that the owners of low-lying ground paid small sums to carters for every load deposited on such ground so that it might be raised to a higher level for building purposes. Of course the carters were not particular as to the quality of the material they thus brought. The neighbours complained in vain of the nuisance occasioned. What became building soil was therefore composed of every kind of filth. Speaking of the soil on one particular site the borough surveyor Mr. Bretland himself admits that "it is of the worst possible description and that in his opinion houses should not be built on it. Mr. Munce admits it might be described as an enormous dunghill. Personal examination satisfied those members of the committee who visited it that it is composed of every description of decaying organic refuse. Now," adds the report of the committee, "it is surely a matter for surprise that much of this condemned ground has already been covered with houses, that plans for streets have been already passed by the Improvement Committee for the remainder, that these streets at the present moment are being laid out, and that plans for houses to be built thereon were recently submitted to the Improvement Committee and a recommendation made to the council to pass them. How, it may be asked, does it happen that the council should be asked to pass plans for houses on ground which the surveyor and the assistant surveyor in their evidence condemn as unfit to build on?" This noxious ground was not removed because, as one of the building inspectors said, "the further you go down the worse it becomes." Then the fact that the use of concrete is recommended to prevent noxious exhalations arising into the houses proves that the ground has not become innocuous. As for the concrete, considering that some subsidence will inevitably occur, it is bound to crack and would not therefore prevent the noxious exhalations from coming through. Even if the concrete remained sound the exhalations would permeate the streets where the children play about and whence the houses derive their air-supply. A list of streets and districts built on town refuse, the contents of ash pits and privies, is given and this is a direct contravention of the Section 25 of the Public Health Amendment Act quoted above.

Under Section 113 of the Public Health Act, 1878, and Section 32 of the Housing of the Working Classes Act, 1890, ample power exists to obtain a closing order for houses that are unfit for human habitation. But on page 16 of the Special Committee's report I find the following strong statement: "Now, it was plainly alleged before us that it is altogether useless to ask the Belfast magistrates to close a house even on the most possible evidence that it was unfit and could not be made fit for human habitation. It was stated that the magistrates ordered, in the face of such evidence, some trifling repairs to be done and then adjourned the case and there the matter ended. This is a serious allegation and if it is true that the justices, by refusing to enforce the provisions of these Acts, have paralysed the sanitary authority in its efforts to improve the dwellings of the people, then the sooner public opinion expresses itself on this subject the better." The report then describes some such places, as, for instance, a row where "there are about eighty inhabitants with only one common privy, so foul that it really cannot be described. The sewage runs into the open court and on wet days is carried into the houses, where it becomes absorbed in the earthen floors." If in such cases the magistrates refuse to give a closing order it is urged that an appeal should at once be taken to the Recorder. "By this means public attention would have been drawn to what, if the allegations of the officials of the Public Health Committee be correct, we cannot describe as other than grave miscarriages of justice on the part of some of our magistrates." It had been urged that action had not been taken because some general scheme was in contemplation. But the special committee argued that by such scheme the ratepayers would "be compelled to practically compensate landlords for the loss of rents which, while the houses are in their present condition, should not be payable. In other words, these general schemes often mean that this unsanitary property should be purchased at extravagant prices by, and developed at the expense of, the general ratepayer. If the houses are unfit for human habitation they should be closed until they are habitable and once they are closed the ground landlord and owners may safely be trusted to develop the ground themselves."

The report then goes on to complain that Belfast was the only important town in the United Kingdom where the Infectious Diseases (Notification) Act was not enforced. As, however, this Act has now at last been applied this grievance may be passed over. The report further complains that the fines imposed for selling milk under the proper standard of quality, margarine for butter, and diseased meat, and for violating the Shop Hours and Factories Act are so light as to be ineffectual, but that "the large fines which the magistrates impose for diluting porter stand out in startling contrast to the nominal penalties imposed on farmers and milk-vendors for diluting milk—the staple food of a large part of our infant population." Then there is no hospital for infectious diseases; and though Section 15 of the Infectious Diseases Act and Section 42 of the Belfast Main Drainage Act require that the corporation should provide a temporary shelter for families who have to leave their homes while undergoing the process of disinfection no such shelter has been provided. With regard to the building of new houses and streets there are not enough inspectors attached to the surveyor's department to see that the by-laws are carried out. "As an example of this lax organisation and supervision we found that in Battenburg-street a sewer had been constructed without any outlet whatever. Into this blind sewer the sewage of five houses flowed for several months, impregnating with sewage the adjacent ground, and it was only when the drainpipes of several other houses were being connected with it that the absence of an outlet became evident. We have no desire to exaggerate the significance of this mistake, but we are of opinion that with better organisation and a more numerous staff such incidents as this would be impossible."

Finally the report of the Special Committee deals with such passages as do exist and they are thought to number about a thousand. Previously to 1878 workmen's cottages were generally built without any back passages at all. The 1878 Act empowered the Improvement Committee to insist on a back passage not exceeding nine feet in width. But in view of this Act any number of plans were drawn up for the building of houses without back passages and these were sanctioned though there was no immediate intention of building the houses. Thus many houses have been built after 1878 without back passages because they were sanctioned before that date. It is obvious that if the authority had been earnest in the matter they would not have sanctioned plans which were drawn up for the evident purpose of defeating the law about to be enacted. From 1878 to 1888 plans were sanctioned which provided for back passages which were only four and a half feet wide, but many of the passages that exist are uncompleted. The law requires that they should be paved, but they are not paved All kinds of garbage were thrown into them and

Digitized by Google

the report states that they are seldom cleaned and become sodden and saturated with filth. In some cases the doors leading on to these back passages have been walled up so that they are useless for the emptying of the ashpits and therefore the filth has to be carried through the houses.

Such are the main features of the remarkable report which was presented to the special meeting of the Belfast Town Council called together by the Lord Mayor on Oct. 22nd, 1896. I have dwelt at great length with this document because it seemed likely to be more convincing than anything I might have said. Here are two aldermen and seven town councillors, inhabitants of Belfast, not casual visitors like myself but men who so far enjoyed the confidence of their fellow citizens that they were elected to the responsible posts they occupied at the time and yet these gentlemen found themselves compelled by the facts of the case to draw up a strong indictment against the very council to which they belonged. But if I have reproduced at length their principal arguments and statements I have also taken pains to ascertain how far the condition of things described as existing in the autumn of 1896 still prevails in the winter of 1897. This enables me to say that there has been some improvement, though unfortunately that improvement is but slight and insufficient.

First, with regard to the number of officials whose duty it is to watch over the health of the town. Instead of one factory inspector there is now in addition an assistant inspector; but even this does not suffice for their district extends for many miles outside the town of Belfast. Six extra sub-officers or sanitary inspectors were added last June, raising the total number to twenty-three. But this includes the common lodging-house inspector, the dairy and cowshed inspector, the inspector under the Food and Drugs Act, and the workshops inspector, there therefore remain only nineteen inspectors available to perform the ordinary duties of an inspector of nuisances. But now that the boundaries of Belfast have been largely extended and include vast suburban and semi-rural districts three of these inspectors have been deputed to attend to these newly-acquired and outlying neighbourhoods. There consequently only remain sixteen inspectors of nuisances for Belfast town. Now the town has been divided into fifteen sanitary districts, each district having about 20,000 inhabitants. Therefore when the report of the Special Committee complains that there is but one sanitary inspector for 30,000 people it will be seen that there is now one or rather more than one inspector for every 20,000 people; but it must also be borne in mind that six out of the sixteen available inspectors for the town are newly appointed and therefore comparatively inexperienced.

What the report of the Special Committee did not notice, though it deeply affects the efficacy of sanitary supervision, is the confusion and conflict of authorities. Belfast is divided into what are called the ten dispensary districts. These districts do not correspond with the fifteen sanitary districts, yet each has its dispensary officer, who is the medical officer of health for his dispensary district. Now this medical officer of health is not appointed by the town council or sanitary authority. He is appointed by the Dispensary Committee, which is not an elected body but is nominated for the purpose of managing the dispensary organisation of the Poor-law guardians. These dispensary medical officers of health receive salaries which are defrayed half by the ratepayers and half by the State, and what makes matters worse they are allowed to engage in private practice. It was this organisation that proved the principal obstacle to the application of the law on the compulsory notification of infectious diseases. The general practitioners objected to notify to the dispensary medical men who were competing against them. The enforcement of the law was only accepted when it was arranged that the notifications should not be sent to the dispensary medical officers but to the superintendent medical officer of health, Dr. Whitaker, who is appointed by the town council. But what is the position of Dr. Whitaker? Nominally he is the head of all things appertaining to the sanitation of the town. Practically he has little or no power and his mission seems restricted to periodically expressing a pious wish in respect to sanitary reform which is as punctually relegated to a pigeon hole and duly forgotten. In one respect Dr. Whitaker can render eminent service. He is independent of private practice so that when the dispensary medical officers fear to make themselves unpopular by insisting on the removal of a bad case to the hospital they apply to Dr. Whitaker, who having no patients to lose takes upon himself this unpleasant task. But here we come to the scandalous fact that there is no hospital for infectious diseases. The patient must be removed to the workhouse infirmary where there is provision made for fever cases and (I believe) 250 beds disposable. There are also a few beds in an isolation ward of the General Hospital, but the practical result is that with the exception of the poor the great mass of fever patients are treated at home.

If a widespread epidemic were to occur it is the Dispensary Committee that would have to appoint extra medical men, provide nurses and beds, and the Poor-law guardians would have to pay. The Public Health Committee of the town council could only instruct their sanitary inspectors to disinfect the houses and assist the dispensary practitioners to remove the patients. Here again we come to another gross piece of neglect. In spite of the precise stipulation of the law mentioned above no shelter has yet been provided, so that when a house is disinfected the inhabitants have to be turned into the street.

With regard to the other grievances I am told that if the sanitary authority were to cement and cover the ash-pits and middens it would appear as if they approved of the system, while their object now is to abolish it altogether. Therefore but little has been done in this direction. Then with respect to the closing of houses unfit for habitation, such houses when closed are broken into, the window frames are torn away for fuel, and they are said to become a greater nuisance than when inhabited. This I must confess seemed to me a somewhat lame explanation. Doubtless such nuisance does arise, but it is not likely to last for long as the owners would soon find some means of rendering their property profitable. As for the unpaved back passages these are in many cases private and have doors. If they were paved the doors would be taken away and they would become public passages. Strangers would enter these passages and commit nuisances. The second condition of affairs would perhaps not be better than the first. The powers of supervision are so limited and the increase of these passages so rapid that it is difficult to keep pace with them.

Notwithstanding, however, these excuses and explanations it is quite clear that much more could and should have been done. It is notorious that too many people in authority have been personally interested in resisting proposed sanitary reforms. But now perhaps a new era is about to dawn upon the town. In consequence of the extension of the borough boundaries another and more numerous council has just been elected. It is to be hoped that the present council will have a keener sense of its responsibilities and a higher appreciation of its duties.

(To be continued.)

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Hospital Saturday and Sunday Funds.

THE annual meeting of the subscribers to the Manchester Hospital Saturday and Sunday Funds was held on the 22nd ult. There has been some falling off in the amount collected which may be attributed to the numerous and special calls made during this year. In 1895, 1896, and 1897 the collections were £8200 12*s.* 8*d.*, £8315 8*s.* 2*d.*, and £8088 4*s.* 1*d.* respectively, while the amounts distributed were: in 1895, £7400; and in 1896 and 1897, £7500 for each year. From some passages in the report it would seem that the members of the Red Cross Society (the working-men's auxiliary to the Fund) in most cases objected to the charges made to patients at some of the hospitals and the committee was requested to ascertain whether (1) the charges would be modified for members of the Red Cross Society in consideration of their subscribing systematically; (2) whether members of the General Committee of the society might visit the hospitals at reasonable times other than the ordinary visiting days; and (3) that the system of making inquiries respecting the circumstances of patients through the agents of the provident society be discontinued. The sub-committee appointed to consider these proposals rejected the third as impracticable until some equally efficient system of preventing abuse was available. With regard to 1 and 2 the views of the Red Cross Society were laid before a sub-committee of the Royal

Digitized by Google

Infirmary Board and the reply was that the board did not see its way to make any concession in favour of any section of contributors to the funds of the infirmary. The point of all this seems to be that many of the working classes do not look on hospitals as charities but as business establishments for the sale of medical and surgical treatment.

Manchester Port Sanitary Authority.

The annual meeting of the Manchester Port Sanitary Authority was held on the 2nd inst. The clerk stated that the regulations as to the notification of infectious cases on shipboard were still awaiting sanction by the Local Government Board and the delay had been considerable. It was decided to call the attention of the board to the matter. The report of Dr. Crooker, the medical officer, showed that 102 inspections of vessels had been made and four re-visitations. Of the ships inspected eighty-five were British, ten Norwegian, four German, and one each Danish, Spanish, and Russian. Insanitary conditions were found in fifteen British and four foreign vessels, but they were of a trivial character and soon remedied.

The Rivers Committee.

The November elections have brought about many changes in the Manchester City Council and in its various committees. The Rivers Committee has lost its chairman, Alderman Joseph Thompson, and Alderman McDougall who declined to serve on it again in the face of the adverse vote of the citizens on the culvert scheme. The former must feel relieved to find himself free from one of the three offices, Director of the Ship Canal Company, Vice-Chairman of the Joint Mersey and Irwell Committee, and Chairman of the Rivers Committee of the Corporation, involving duties more or less antagonistic He is succeeded as chairman by Sir Bosdin Leech.. The sewage difficulty still remains and on the 26th ult. an application was made on behalf of the corporation at the Manchester county police-court for an extension of time for the construction of the sewage works at Davyhulme. Mr. J. M. Yates, the stipendiary, made some pertinent remarks, saying that the summer was coming on and people would like to know that something was being done to make the canal sweeter and that though Manchester might have to expend a large amount of money its wealth was very great. He felt that the difficulty was that the corporation did not want land filtration and the Local Government Board did. An adjournment to April 1st was suggested, but he thought that would be rather bad, and that seeing "there was a new Rivers Committee who were prepared to look the matter fairly in the face he thought the best course would be to adjourn till March 25th." It is to be hoped that the process now being carried on at Exeter will be carefully watched, for if successful—and appearances are favourable—it promises to go a long way in solving the sewage difficulty.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Opening of the M'Ewan Hall of the Edinburgh University.

THE formal transfer of the M'Ewan Hall to the University authorities was made on Dec. 3rd by the University Buildings Extension Trustees. The event was marked by an academic ceremonial of an unusually imposing character; in fact, no such ceremonial has been seen since the celebration of the tercentenary of the University. A description of the hall has already been given in THE LANCET and in its completed form it has more than realised the most sanguine expectations. The design, the richness of the decorations, and the harmonious blending of colour formed a suitable setting for the ceremonial of Friday. The area of the hall and the first gallery were occupied by graduates in academic costume and by those of the public who had been fortunate enough to receive invitations. The topmost gallery was occupied by students. The platform and the front rows in the area were reserved for members of the University Court, professors, civic authorities of the city, and other important personages including representatives from other universities. The chair was occupied by the Chancellor of the University, the Right Hon. A. J. Balfour, M.P. The proceedings were opened by the singing of the Hundreth Psalm and the reading of appropriate prayers. Thereafter Mr. M'Ewan, M.P., the donor of the hall, indicated the reasons which had led him to offer to build such a hall for the University and then handed the transfer deed of the hall to the Chancellor. The Chancellor in suitable terms acknowledged the gift. The Lord Rector, Lord Balfour of Burleigh, then spoke as chairman of the University Court. Next Principal Sir William Muir spoke as representing the Senatus Academicus of the University, the Lord Provost on behalf of the City, and Professor Sir William Turner on behalf of the trustees. After this the Dean of the Faculty of Law presented Mr. M'Ewan to the Chancellor for the honorary degree of Doctor of Laws. An address was then presented to Mr. M'Ewan by the Students' Representative Council on behalf of the students. Both before the ceremony and as the procession from the platform was leaving the hall Dr. A. L. Peace played selections on the grand organ. It may be mentioned that the hall cost about £115,000. The day was observed as a holiday in all the Faculties and on the previous evening the students had a very successful torchlight procession.

Edinburgh Royal Infirmary.

At the meeting of managers on the 6th inst. Mr. John Walcot, convener of the House Committee, made a statement dealing with the expenditure for the past year. The ordinary expenditure as compared with 1895-96 showed a decrease of £144 on five items, while on fourteen other items there was a gross increase of £2048, leaving a net increase of £1904. One item in this was the parochial assessment, this being the first time in the history of the infirmary that payment had been exacted. A second item was under the head of furnishing and repairs and the third large item was under the head of medical expenditure. The last included £91 for serum. He said they could not justly complain of that. It was to the honour of the infirmary that in it the poorest patient might benefit by skill and remedies which men of wealth could only obtain by heavy payments. There had also been a considerable increase in "dressing." This might have been unavoidable but it was as stern a duty to prevent excess as to secure sufficiency. During the year the list of nurses and servants had been increased by twenty-seven. The daily average of indoor patients was 703 and the total number of outdoor patients was 28,000. He referred at some length to the progress the infirmary had made during the past ten years and they could not conclude that they had reached the limit of demand on their space and resources. Their experience of a generous and sympathetic public warranted them to go forward in the spirit of enterprise and confidence while exercising due caution and economy.

Appointment of Assistant Physician to the Edinburgh Royal Infirmary.

At the meeting of the managers on Dec. 6th the vacancy on the staff of assistant physicians to the infirmary was filled by the appointment of Dr. J. J. Graham Brown.

Glasgow Southern Medical Society.

This society met on Dec. 2nd, the President, Dr. Jas. W. Allan, being in the chair. Dr. J. Walker Downie read a paper on the Treatment of Nasal Obstruction and Asthma due to Turbinal Hypertrophies, which subject was dealt with very fully. Wax casts and specimens were shown illustrating the paper. The "spokeshave" of Carmalt Jones was preferred for removing the turbinate to the use of the cautery or wire-snare, but Dr. Downie urged that the bone should not be entirely removed; an anterior or posterior inferior turbinotomy should be performed, or both, leaving an intermediate portion. To this great importance was attached, the patient escaping pharyngitis sicca and other discomforts following complete removal of the bone. Hæmorrhage in all cases had easily been controlled, only one case in twenty requiring plugging. Dr. MacMillan, Dr. Thomas Forrest, Dr. Hamilton, and others discussed the paper. Mr. L. Burges exhibited photographs of a case of Syphilitic Disease showing the benefit of large doses of iodide of potassium.

University of Aberdeen.

Aberdeen University Court estimate that they will require a further sum of £30,000 to complete the University buildings extension scheme. They have asked the Aberdeen town council to contribute an additional £10,000, and intend to apply to the Government for a further grant of £10,000, and to the general public for the balance. The students' representative council has in polite terms remonstrated against having so many examinations on Saturday as has hitherto

Digitized by Google

been the case. The students' representative council has also resolved to petition for the abolition of the present "academic costume" at the Arts classes and favour the wearing of differently coloured tassels for the various years. A large fisheries exhibition is to be held in Aberdeen in the summer of 1899 and Professor Alleyne Nicholson has promised the coöperation of the University in the movement so far as its available funds will permit.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Medical Officers of the Tirah Expedition.

THE *Irish Times* of the 3rd inst. contains the following statement: "The principal medical officers arranged under the supervision of Surgeon-Major-General A. A. Gore, F.R.C.S.I., Principal Medical Officer of Her Majesty's Forces in India, are Surgeon-Major-General G. Thomson, C.B.; Surgeon Colonel G. M'B. Davis, D S.O.; Surgeon-Colonel E. Townsend; Brigade-Surgeon-Lieutenant-Colonel W. R. Murphy, D.S.O.; Brigade-Surgeon-Lieutenant-Colonel R. G. Thomsett; Brigade-Surgeon-Lieutenant-Colonel W. E. Saunders."

The Children's Hospital, Temple-street, Dublin.

The annual meeting of the friends and supporters of the Childrens' Hospital was held on the 2nd inst., the Most Rev. Dr. Donnelly, Bishop of Canea, in the chair. The report, which was of a very satisfactory character, was read by Dr. Joseph O'Carroll, and after the meeting had been addressed by many speakers, including Sir Percy Grace, Bart., D.L., the proceedings terminated.

The Ulster Medical Society.

The annual dinner of the Ulster Medical Society was held in Thompson's Restaurant, Belfast, on Nov. 30th. The chair was occupied by the President, Dr. J. A. Lindsay, and there were seventy members and guests present. After an excellent dinner the chairman proposed the toast of "The Queen" and "The Prince and Princess of Wales and the other members of the Royal Family," referring very happily to the progress made by medical science in Her Majesty's reign and to the fact that the heir apparent was now, thanks to the Royal College of Physicians of London, able to add another *rôle* to the many parts he played. The next toast, "The Lord-Lieutenant and Prosperity to Ireland," proposed by the President was replied to by Professor Byers, who said he was sure they all were pleased to notice that in recent times there was less political strife and sectarian bitterness in Ireland, and he hoped the time was soon coming when all parties in their native country, irrespectively of creed or political opinion, would work together for the good of Ireland, just as in that room medical men of all religions and opinions met around one common board, united in the brotherhood of the medical profession. Brigade-Surgeon McFarland proposed in complimentary terms the toast of "The Queen's College and Belfast Medical School," referring to the very great interest the President of Queen's College had always taken in the medical profession. Dr. Hamilton (President of Queen's College), in his reply, thanked the members very warmly for the kind way in which they had received the toast of his health and said the medical faculty was the "predominant partner" in the College. He gave very interesting figures showing the growth of the medical school. Dr. O'Neill, surgeon to the Royal Hospital, and Dr. J. Lorrain Smith (Lecturer on Pathology at Queen's College) also replied. Professor Symington proposed "The North of Ireland Branch of the British Medical Association" to which Professor Whitla (ex-President)—who apologised for the absence of Dr. Gray, of Armagh (this year's President)—and Dr. John Campbell, the secretary, replied. "Our Guests" was given by Dr. Dempsey, J.P., who referred specially to the visit to Belfast of the Special Commissioner of THE LANCET. Dr. Graham having thanked the members for coupling his name with the toast, THE LANCET Special Commissioner, in responding, said that he was the more gratified by the reception accorded him as he could not but look upon himself as a bird of evil omen. After following the cholera for three years from town to town in Europe he had pursued typhoid fever from Maidstone to Lynn and from Lynn to Belfast. His bed had not always been a bed of roses, and although a rose by any other name would smell as sweet, the courts and alleys of Belfast, whatever might be their names, certainly did not suggest the perfume of flowers. The fact, however, as shown by that banquet, that the medical profession in Belfast stood shoulder to shoulder, in spite of their deep religious and political differences gave good hope that the necessary sanitary reforms would be ultimately accomplished. The Ulster Medical Society had a high mission to perform—that of preserving the health of the public and of defending the dignity and honour of science. Mr. Seddall (the Assistant Commissioner of Police) also replied. The President of Queen's College then in very laudatory terms proposed the health of the President of the Ulster Medical Society referring to his high literary, professional, and academic status. The toast was received most warmly and Dr. Lindsay having replied the health of the secretary of the Ulster Medical Society was given by Dr. Campbell and replied to by Dr. Colville. During the evening some capital music was rendered by a stringed band and songs were contributed by Dr. McKisack and Dr. Leslie, while Dr. J. S. Morrow gave an excellent recitation of one of Rudyard Kipling's poems.

Health of Belfast.

During the past five weeks (from Oct. 21st to Nov. 24th) 424 cases of zymotic diseases were notified—viz.: typhoid fever, 351 cases; simple continued fever, 45; scarlet fever, 36; erysipelas, 24; diphtheria, 19. It will thus be seen that typhoid fever still prevails. The deaths from zymotic diseases were 67, those from phthisis 76, and from diseases of the respiratory organs 165, making the very large total of 241 from these two causes. In the mortality from zymotic diseases and chest affections the Registrar-General's last statistics show that Belfast occupies the unenviable position of being at the head of the list. During the past month the cases of typhoid fever (as well as the deaths from that disease) were less than in the preceding four weeks.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Etiology of Appendicitis.

THE theory of Dieulafoy as to the part played by the "shut sac" (*vase clos*) in the matter of appendicitis has received confirmation in a paper read by MM. Hatmann and Mignot before the Society of Surgery at the meeting held on Nov. 17th. They cited the case of a boy, aged sixteen years, upon whom laparotomy in the iliac region had been performed for an appendicular abscess. Three months later he was seized with violent abdominal pain and constant vomiting and the appendix was accordingly removed. This organ, which was coiled upon itself, was found to have at its extremity a very minute opening, while at the level of the upper third with the two lower thirds the canal for the space of half a centimetre was obliterated and converted into a fibrous cord. Microscopic sections taken at this level presented no trace of any canal. Two cultures were made with the mucus from the two portions—the obliterated and the patent—and the first was found to contain colon bacilli of a far more virulent quality than those present in the other portion—i.e., that above the obliteration. This is the first demonstration that has been made of such increase of virulence. MM. Dieulafoy and Caussarede have repeated their experiments and reported identical results at the meeting of the Hospitals Medical Society held on Nov. 26th. They brought forward the case of an obliterative acute appendicitis in which the closed portion of the appendix was absolutely shut off from the free portion of the appendicular canal. Two bouillon cultures were prepared, the one with fluid taken from the free portion of the canal, the other with a like quantity from the shut off portion, and both cultures were found to contain quantities of the colon bacillus. Twelve guinea-pigs of equal weights were then inoculated, six with culture No. 1 and six with culture No. 2. These latter all died while the former remain in perfect health. Moreover, appendicitis is not merely an infection but an intoxication. When guinea-pigs were injected not with the culture as a whole but with the filtrate from them, those injected with the filtrate from No. 1 remained well, but out of three guinea-pigs injected

Digitized by Google

with the filtrate from No. 2 two died with all the symptoms of toxic poisoning. Appendicitis is, then, a toxic infection.

The Shuttle Bacillus.

At the meeting of the Hospitals Medical Society held on Nov. 26th M. Barbier described a simple, short bacillus which he calls the "shuttle bacillus" (*bacille en navette*) and which he has met with in certain throat affections. Experimental investigation still has a good deal to say about that class of bacillus called "short" which is met with in patients presumably the subjects of diphtheria. Some present the characters of the bacillus of Löffler, others are non-virulent, and so on. The organism described by M. Barbier must not be confounded with these. It is bellied out in the middle, fining down towards the ends, shorter than the diphtheritic bacillus and thicker than the "short" diphtheritic bacillus, and when cultivated gives a warty growth on the surface of glycerinated gelatin. It is always found in clusters and is not poisonous to guinea-pigs under conditions in which the diphtheritic bacillus is so. Its special habitat is the nose and it is found in 6 per cent. of throat affections. Those caused by it are either membranous or simply inflammatory. The first class have a suspicious aspect and resemble the serpiginous type of sore-throat; the membrane keeps on returning or else persists in spite of the employment of antitoxic serum which has apparently no action. The patient's general health remains good with no sign of any intoxication. In fine, the shuttle bacillus is an accidental parasite and the sore-throats where it is found are either cases of true diphtheria or else septic, its presence not being essential to these affections.

The Night Medical Service.

A circular dated November 27th has just been issued to the officials in charge of the medical night service by the Prefect of Police containing new instructions having their origin in the Laporte case. For the future any medical man when summoned to a case at night, under this service whether the case be a midwifery one or any other, can claim the help of a colleague and both medical men will receive the fee allowed by the prefecture of police for night attendance. This decision was arrived at upon the report of a case sent in by Dr. Guyon-Dessaigne, the head of the Beajon Maternity Hospital. A midwife had summoned one of the night medical officers and he, to avoid the responsibility of the difficult operation of delivering the patient sent her to the hospital, on arriving at which she died though probably a timely intervention would have saved her life.

Opening of the Boucicaut Hospital.

On Dec. 1st the President of the Republic opened the magnificent hospital built at a cost of 8,000,000 francs from a bequest of the late Madame Boucicaut. The opening, which was to have taken place on July 14th, was delayed owing to some of the internal fittings not being completed. Every modern improvement is contained in the building; it is lighted with electric light and has a lift on every floor. The floors are all of grey tiles and at the end of every ward is a verandah prettily decorated with flowers and plants for the use of the patients, a verandah which is also to be used for smoking. Lifts are provided for bringing up food and for other purposes and in the basement they all communicate with a little railway and a subterranean passage so that none of the working of the hospital is obvious from the outside.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Brindisi Route.

A QUARTER of a century ago France, among other disasters of her war with Germany, lost the transmission of the Indian mails, the contract being ceded to Italy who thus secured a golden opportunity of increasing and perpetuating her profits derived from tourist traffic between West and East. But how perfunctorily Italy has risen to the occasion no one, certainly no invalid, who has tried the "Brindisi route" can have failed to realise. The inconveniences, or worse, of landing or getting on board at Brindisi; the occasional annoyances of quarantine; the baggage robberies, frequent enough to be almost systematic, coming after customs-house "formalities" the most vexatious in Europe; above all the insanitary condition of Brindisi itself, of Bologna, of Milan, where destructive epidemics are combated rather by a "conspiracy of silence" than by appropriate measures vigorously applied, contribute to form an *ensemble* of deterrents culminating in the imminent forfeiture by Italy of the concession she has so long enjoyed and the loss of that Anglo-Indian traffic from which she derives so much of her revenue. She has had severe enough lessons of late as to the folly of her colonial enterprises and of her sacrificing so much to an army and navy beyond her requirements, certainly beyond her means, but the contemplated return to the French Republic of the privilege taken away from France in 1872 is perhaps the sternest rebuke that could have been administered to her. Italy may yet, so say her official organs, retain her "Brindisi route," but only by prompt and effective abatement of the abuses so long complained of, prominent among them being that "neglected sanitation" of which she has often enough experienced the Nemesis.

A Government "Anthropometric Office."

That Italy cannot cope with her crime is only too clearly set forth in her periodical readjustment of her "Pubblica Sicurezza," a system which is once more to receive a drastic overhauling at the hands of the Di Rudini administration. One of the proposals of the Premier's forthcoming "Progetto di Riforma" is the institution under Government of an "Ufficio Antropometrico," an office, that is to say, which will assist the police in their task of identifying criminals. Not for the first time has such an auxiliary to the "Pubblica Sicurezza" been brought before the Italian Government. Here in Rome rather more than eleven years ago at the memorable Congresso Penitenziario M. Alphonse Bertillon, director of the "service d'identification" in the police system of Paris, placed beyond question the importance of identification by means of anthropometry, whereby a criminal may ever after be recognised and identified by measurements taken on his person, measurements between two osseous points remaining unaffected by time or age. So practised, anthropometry recommends itself not only to the judiciary authority, not only to the police, but even to the criminal himself. For such an one after a first condemnation has a powerful deterrent against a relapse into nefarious courses in the knowledge that the measurements of his person are always within reach, that no disguise or self-manipulation can neutralise them, and that brought once more under police scrutiny he does it with the absolute certainty of being identified, re-convicted, and sentenced to a more exemplary punishment than before. Flight to a foreign country cannot avail him. The fatal measurements clog him from police authority to police authority and bring him to justice at last. Anthropometry, indeed, through its office attached to the Prefecture of Police in Paris more than justified its practice by identifying between 1883 and 1890 as many as 3017 criminals in France alone and has only to be adopted south of the Alps to find a yet larger field for its exercise and yet further opportunities for perfecting itself. Nowhere so warmly as in Italy will its coöperation be welcomed as nowhere more than in Italy have the substitutes for it so miserably failed. Take photography for an example. Not without its efficacy when the number of criminals is small how can photography succeed when the identifying photograph has had to be sought from among thousands upon thousands? As a humble auxiliary it has its uses, but even these are minimised by the resources of the criminal who to say nothing of minor facial or corporeal changes does not shrink from inducing vast cicatrices on the forehead, across the nose, with loss of the integument; while even emaciation will alter appearance and expression beyond all recognition. M. Bertillon, no doubt in his anxiety to retain the photograph as an auxiliary, has proposed new applications of it, using it for identifying stature, occipito-frontal diameter, and bi-parietal diameter, down to the length of arms and fingers, legs and feet. But Italian criminologists have pointed out how easily these indications may be modified, not only by the "oscillations of disease" but by the artifice of the individual under examination. They fall back, therefore, with increased emphasis on anthropometry pure and simple. One of the school—Signor Anfosso, I believe—invented the "Tachy-Anthropometer" (so-called from the celerity with which it works) which, avoiding some of the objections to the photograph, was not free from others of its own; but now as used under the "systema craniografico" Anfosso's

Digitized by Google

apparatus may be considered as nearly perfect, the craniographic relief obtained, however quickly, being seldom or never vitiated by any flaw and even then the "margin of error" does not exceed a millimetre, if so much. The diagram, directly superimposed on the head of the subject, guarantees precision, whereas with the "millimetric measurements the only way of verifying their exactness lies in repeating them." The system of craniological identification has the still further advantage of "presenting a multitude of differentiating points between individual and individual" and of "helping the judiciary as well as the police identification." "Nothing more easy," says Dr. G. E. Curátolo (Professor of Gynæcology in the Roman University, to whose masterly paper on the subject the reader is referred), "nothing more easy than to add to the passport of an individual the craniogram which, better than any photograph, guarantees his identity. The apparatus with which the cranial curve is obtained consists of two metallic "reguli" carrying a "listarella" (small strip) of lead. This is supported on the head along the antero-posterior curve, starting from the base of the nose to the inferior point of the nucha and is sustained (as already said) by the two "reguli" which, moving on a pivot carry it over a vertical plane. On this rests a sheet of paper prepared with picrate of potash. When the "listarella" touches the paper, a current of electricity intervenes which, decomposing the solution at the points of contact, determines a coloured line which reproduces the curves of the "listarella" and hence that of the head. The "Tachy-Anthropometer," soon to be in working at the Government "office of Anthropometry," will according to Lombroso and others engaged in perfecting it, assist materially the judiciary and the police authorities, while it will contribute to enlarge the area of criminal anthropology as a science. "If," adds Professor Curátolo, "after eleven years from the Congress held in Rome at which Bertillon read his paper we see the establishment of an institute like that which in the Paris Prefecture of Police has operated so successfully since 1883, the praise is due to the Marchese di Rudini who in providing for the 'Pubblica Sicurezza' in the capital of the kingdom will have performed the further service of meeting a long-felt scientific want."

Dec. 4th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Diseases of the Liver.

A HIGHLY interesting paper on the Prognosis and Treatment of Diseases of the Liver has been read by Dr. Kolisch at a meeting of the Vienna Medical Club. Disease of the liver is as a rule only a part of a morbid condition such as sepsis, phthisis, or phosphorus poisoning; but there may on the other hand be local affections of the liver—carcinoma, for instance—which by the nature of the lesion influences the prognosis. In uncomplicated affections of the liver the prognosis depends on the proportion of liver cells which no longer fulfil their functions and on the derangement of the normal metabolism. The secretion of urine containing bile pigment and throwing down much sediment is a grave symptom; scanty urine is more unfavourable, but polyuria shows that the state of the liver is improving. Urobilinuria is a very important sign. Clinical experience shows that a great many forms of jaundice begin and end with it, but that bilirubinuria prevails during the intervening period. Urobilin is not formed in the liver, but is produced in the intestine by the reduction of the bilirubin which originates in the liver and is absorbed by the intestine. The theory that urobilin is formed when the liver is diseased is disproved by the fact that a minute amount of urobilinuria is normal, and also by the occurrence of bilirubin in the urine in cases of acholia. But the theory that urobilin is formed in the intestine does not explain some cases of urobilinuria in diseases of the heart, in fever, in the onset and disappearance of jaundice. Dr. Kolisch's theory of urobilinuria is as follows. The bile is always being secreted by the liver and absorbed by the intestine (circulation of the bile). The urobilin which is normally formed in the intestine from bilirubin also circulates in the same manner. Urobilin is more easily diffusible than bilirubin, and under ordinary circumstances a small portion of it makes its way through the liver cells and appears in the urine (normal urobilinuria). Under pathological conditions a slight impairment of the function of the liver cells permits the passage of an increased amount of urobilin which appears in the urine (pathological urobilinuria), whereas the bilirubin is retained. Dr. Kolisch's experiments show that the so-called cholæmic coma is due to an increase of the ammonia compounds, especially carbamic acid, circulating in the blood and he therefore believes that the amount of albuminous food should be reduced in serious disorders of the liver such as cirrhosis with destruction of the liver tissue. In order to promote the elimination of toxic substances from the organism he administers diuretics, especially those which are antiseptic and act on the bowel. Medicines which assist the disintegration of albumin—salicylic acid for instance—are to be avoided. As a cholagogue he uses ox-bile and its preparations.

Hay Fever.

At the same meeting of the Medical Club Dr. J. Müller discussed the question of hay fever. He said that patients were able to predict an attack and that in a great many cases it occurred yearly. It could be proved that pollen entering the respiratory tract was the cause of the disease. The patients are very nervous and a great many show gastric symptoms. The attack begins with itching in the nose or sometimes in the eyes, accompanied by convulsive movements of the eyelid. This was followed by spasmodic sneezing and a profuse secretion of serous fluid from the nose. The mucous membrane of the nose was swollen, the conjunctiva was injected or chemotic, and sometimes there were œdema of the eyes, vertigo, photophobia, pain in the forehead, in the temples, at the back of the head, and in the teeth. There is a causal relation between hay fever and gastro-intestinal symptoms. Dr. Müller adopted energetic local treatment of the nasal mucous membrane, which he touched with a 20 per cent. solution of nitrate of silver, and after some days irrigated it with seven litres (twelve pints) of Karlsbad water, followed at last with a mixture consisting of three grammes each of menthol and resorcin and fourteen grammes of spirit of wine. The result was the detachment of the diseased mucous membrane and disappearance of the secretion.

Legal Sanction of an Unqualified Practitioner.

The permission to practise medicine granted to an unqualified person named Stadlbauer under the circumstances described by me in THE LANCET of Nov. 13th, p. 1290, has elicited several protests. At the last meeting of the Vienna Medical Society Professor von Schrötter proposed the following resolution which was unanimously adopted:—"The Medical Society expresses its sympathy with the Upper Austrian Medical Chamber and adds its protest against the 'venia practicandi' granted to Stadlbauer. At a time when it is being discussed whether five years' training is sufficient for medical students, when examinations are being made more stringent, and when a two year's practical course is about to be made compulsory for those who have obtained their M.D. degree the authorising of a shopkeeper to practise medicine seems to be a mockery of recognised methods."

Rioting in the University.

Last week the University of Vienna was the scene of riots such as have not occurred since the memorable year 1848, the exciting cause being the resentment of the German party against the so-called "language decrees" ("Sprachenverordnungen"), by which Count Badeni endeavoured to conciliate the Slavs. On Nov. 29th about 4000 students assembled in the aula of the University, shouting "Abzug Badeni!" (Away with Badeni!), the consequence being that the police entered the building in defiance of a longstanding privilege. The students then went to the Houses of Parliament, where there was a regular battle between them and the police, and the number of wounded students was very considerable. Count Badeni eventually yielded. A great many professors of the four faculties of the University protested energetically against his policy.

Obituary.

WILLIAM FETTES MURRAY, M.D. ST. AND., F.R.C.S. EDIN.

FORFAR has sustained a severe loss by the death of its most prominent medical man, Dr. William Fettes Murray, who passed away on Nov. 28th, aged fifty-nine years. He received his education at Forfar Academy and the University of Edinburgh and after holding the post of resident physician at the Birmingham Maternity Hospital settled down in practice at Forfar some thirty years ago. He was one of the first to insist upon the danger of the transmission of tuberculosis by milk and meat from animals infected with that disease and had many a fight with the local authorities by reason of his opposition to the sale of animals known to be tuberculous. In 1874 he was appointed medical officer of health for the burgh. He enjoyed a large private practice and was a universal favourite. He was closely identified with the management of the Forfar Infirmary and opposed to the utmost of his power a proposal that the upper wards of the main building should be utilised for the reception of infectious cases. He was a great cricketer and fond of sport of all kinds. The funeral took place on Dec. 9th.

SIR ANTHONY BROWNLESS, K.C.M.G., M.D. ST. AND., M.D. MELB., F.R.C.S. ENG.

BY the death of Sir Anthony Brownless, which occurred on Dec. 3rd, Melbourne loses one of her most distinguished citizens and the University her Chancellor. He was the only son of the late Anthony Brownless, of Goudhurst, Kent. He received his education at St. Bartholomew's Hospital and at the University of Liege. In 1841 he was admitted a Member of the Royal College of Surgeons of England and in 1846 took the degree of M.D. at the University of St. Andrews. Until 1852 he practised in London as a physician, but he then went to Victoria, where he was elected physician to the Melbourne Benevolent Asylum. Two years later, in 1854, he was elected physician to the Melbourne Hospital, a post he held for twelve years, and on his retirement in 1866 was appointed consulting physician and life governor of that institution. To him was due the founding of the medical school of that University and he was the first on whom she conferred the degree of M.D. He was elected Vice-Chancellor of the University for twenty-nine years, in succession and in 1887 when Dr. Moorhouse the present Bishop of Manchester, was chosen for that office Dr. Brownless succeeded him as Chancellor. He held the degree of LL.D. in addition to that of M.D. from both the University of St. Andrews and Melbourne. In 1870 the Pope made him a Knight of St. Gregory the Great and in 1883 a Knight Commander of the Order of Pius. In 1884 he was elected a Fellow of the Royal College of Surgeons of England. Some years later he was created a K.C.M.G. He was also a J.P. for Victoria and had been a member of several important Government commissions. He was twice married, first in 1842 to Ellen, daughter of Mr. W. Hawker, M.D., of Charing, Kent; she died in 1846; and secondly in 1852 to Anne, daughter of Mr. William Hamilton, Captain, Rifle Brigade, of Eden, co. Donegal.

JAMES MURRAY, M.B., C.M. ABERD.,

SURGEON-CAPTAIN, INDIAN MEDICAL SERVICE.

WE have to record the early death of Surgeon-Captain James Murray at the Ripon Hospital, Simla, on Nov. 8th, 1897. James Murray was educated at the Chanonry School (Gymnasium) and the University, Aberdeen, graduating M.B., C.M. in 1886. He joined the Indian Medical Service in the following year, passing out third from Netley and gaining the Parkes' Memorial Medal. On proceeding to India he was appointed to the 15th Bengal Cavalry and was with this regiment in cholera camp during the hot weather of 1888. It was at that time that he first suffered from dysentery, the disease which ultimately led to his death. With his regiment he saw service in the Black Mountain expedition of 1888 and obtained the medal.

In 1889 he was appointed the colleague of Dr. Watt during the preparation of the "Dictionary of Economic Products of India," receiving the thanks of the Government of India. In 1891 he was appointed to the newly-established Professorship of Pathology in the University of Lahore and the rest of his life when free from illness was devoted to the organisation of his department. Those who were brought in contact with Surgeon-Captain Murray during this period will appreciate how much his heart was in his work. He engaged in teaching with his characteristic enthusiasm, and made a high reputation as demonstrator and lecturer. His clinical skill, which was of the highest order, rapidly brought him a consulting practice in the Punjab. In 1893-94 he had to take long sick leave home as the result of chronic dysentery and again in Australia in October, 1896. While in Melbourne symptoms of abscess of the liver appeared requiring operation, but he returned to his post improved in health and continued his duties. At the end of last hot season the symptoms of dysentery and hepatic abscess recurred and on going to Simla, in spite of rest and an apparently successful operation, he gradually succumbed. Surgeon-Captain Murray, in addition to possessing ability of high quality, was one of the most amiable of men and truest of friends. His death is mourned by his comrades and numerous friends in India as well as by old friends at home who will always have his friendship in loving memory.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Edward S. Bunker, Professor of Pathology in Long Island College Hospital, Brooklyn.—Dr. Müller, formerly teacher of Children's Diseases in Moscow University.—Dr. Joachim Voss, formerly Professor of Anatomy and of Forensic Medicine in the University of Christiania.—Dr. Marc Olivet, formerly Professor of Mental Diseases in Geneva.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Amsterdam:* Dr. G. MacGillavry has been qualified as *privat-docent* of Dermatology and Syphiligraphy.—*Bologna:* Dr. Francesco Roncati has been appointed Professor of Clinical Psychiatry.—*Groningen:* Dr. J. Nijhoff, of Amsterdam, has been appointed Professor of Midwifery and Gynæcology, in succession to Dr. Döderlein, who goes to Tübingen.—*Jena:* Dr. M. Matthes and Dr. A. Witzel have been appointed Extraordinary Professors of Internal Medicine and Odontology respectively.—*Königsberg:* Dr. Jäger, of Stuttgart, has qualified as *privat-docent* of Hygiene.—*Rostock:* Dr. Th. Axenfeld, of Breslau, who together with Dr. von Hippel recently gained the Graefe Prize of the German Ophthalmological Society, has been appointed Professor of Ophthalmology, in succession to Dr. R. Berlin, who has resigned.—*Sienna:* Dr. Benedetto Monpurgo, of Cagliari, has been appointed Extraordinary Professor of General Pathology.—*Toulouse:* Dr. Abelous, *agrégé*, has been appointed Professor of Physiology.—*Warsaw:* Dr. A. Grigorieff, formerly of St. Petersburg, has been appointed Professor of Forensic Medicine.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, MARYLEBONE-ROAD, N.W.—This hospital, the largest of its kind in Great Britain, is making a Christmas appeal. It received 1151 patients into its wards last year and in addition attended 1122 patients at their own homes. The expenditure for the year amounted to £4300 while the income reached £3600 only, this leaving a deficit of £700. To meet the great pressure on the accommodation of the hospital an extension is being carried out and a new nurses' home will shortly be commenced. For these works upwards of £12,000 will be needed. The Committee of Management earnestly appeal for contributions to both the building fund and the general maintenance fund which may be sent to the bankers, Messrs. Cocks, Biddulph, and Co., 43, Charing-cross, S.W.; or to the Secretary (Mr. Arthur Watts) at the hospital. Gifts of clothing for mothers and infants will also be much appreciated.

WATER-SUPPLY OF SHANKLIN.—The Local Government Board has sanctioned the scheme for procuring a supply of water from the springs at Wroxall.

ON Dec 1st, at Horfield, Bristol, a complimentary dinner was given to Mr Colston Wintle, L.R.C.P. Lond., M.R.C.S. Eng., who was returned at the head of the poll for Horfield Ward at the recent municipal election.

ON Dec. 3rd Sir Squire Bancroft gave a reading in Cardiff on behalf of the Seamen's Hospital building fund and the Cardiff Infirmary. Lord Tredegar presided over a large audience and was supported by the bishop of the diocese, Judge Grantham, and others.

OYSTERS AND TYPHOID FEVER AT TRURO.—At the meeting of the Truro City Council held on Dec 2nd the medical officer of health (Mr. E. Sharp, M.R.C.S. Eng., L.S.A., J.P.) reported upon two recent cases of typhoid fever and stated that there was a strong probability that they were attributable to the eating of unwholesome oysters.

BRISTOL CONVALESCENT HOME.—At a committee meeting of this fund held on Dec. 2nd the mayor announced that the total amount of contributions was £82,000. It was thought advisable to invest the money until it was needed for the purposes of the scheme and a committee was appointed with that object.

WALTON CONVALESCENT HOME, NEAR CLEVEDON.—During the past twelve months 341 patients have been admitted to this institution, being an increase on the previous year. The working expenses exceeded the income by £18, although £100 had been received for reducing the mortgage existing on the institution.

THE PROPOSED NEW INFIRMARY AT BATH WORKHOUSE.—A long discussion took place at the meeting of the Bath board of guardians, held on Dec. 1st, when it was eventually decided to rescind the resolution adopted three weeks ago to erect a new detached infirmary at the workhouse to cost £40 000. It was contended that the resolution was carried without due consideration.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.—At the monthly meeting of the President and Fellows held on Friday, Dec. 3rd, 1897, the President admitted to the Licence in Medicine Richard Arthur Jackson, M.R.C.S. Eng., who had been successful at a special examination held on Thursday and Friday, the 2nd and 3rd inst.

SANITARY INSPECTORS' ASSOCIATION.—At the recent meeting at Newton Abbott of the western branch of the Sanitary Inspectors' Association the President (the Right Hon. C Seale-Hayne, M.P.) maintained that inspectors should be placed in a position independent of local pressure so that they could carry out their duties in a free and independent manner.

UNIVERSITY COLLEGE OF WALES, ABERYSTWITH.—At a meeting of the council of this College held last week a letter was read from the Old Students' Association offering to provide a scholarship of £40 per annum, tenable for two years, at the College by a former student being a graduate of one of the universities of the United Kingdom. The scholarship is intended for the encouragement of higher study or research.

THE LATE MR. H W. FREEMAN.—The funeral of the late Alderman H. W. Freeman, F.R.C.S. Irel., J.P., of Bath, which took place in the Landsdown Cemetery on Dec. 3rd, was very numerously attended by fellow citizens and friends. The mayor and corporation attended in state and the committee of the Royal United Hospital were also present. The majority of the members of the profession of Bath were represented and amongst others who attended were Earl Temple and Canon Quirk, rector of Bath.

POISONING CASE AT BRISTOL.—At the Bristol Assizes held on Nov. 29th a man, aged twenty-five years, described as a servant to a veterinary surgeon, was charged with the manslaughter of his brother by administering nine grains of morphia. The deceased was intoxicated at the time and prisoner gave him the drug in order "to quiet him." The prisoner, who pleaded guilty, was discharged in his own recognisances to appear for judgment if called upon, Justice Hawkins remarking that he should never call him up to receive sentence.

WEST OF ENGLAND EYE INFIRMARY, EXETER.—An anonymous donor has given £2000 to the building fund of the West of England Eye Infirmary. Exeter.

DIPHTHERIA IN LONDON.—In the four-weekly period ended Nov. 6th the amount of diphtheria notified in London was excessive. In fact it is necessary to go back to the four weeks ended Dec. 28th, 1895, before finding a similar period having a weekly average higher than that for the four weeks first named. In the 1895 period the total of notifications including duplicate certificates was 1941 and the weekly average 485. In the period ended Oct. 9th of this present year the actual total was 1169 (the several weekly numbers being 267, 309, 290, and 303) with a weekly average of 292. But in the four weeks ended on Nov. 6th the total was 1336, made up of 351, 363, 319, and 303 as the constituent totals and the weekly average as high as 334 cases. In the earlier of these recent periods all save one of the sanitary areas in London were invaded; seven districts had 50 cases and upwards each with an aggregate of 469; and other 5 invaded areas had only 17 cases in all. In the later period all districts were invaded; 10 districts had 50 cases and upwards each with an aggregate of 700 attacks or more than half the total for the 43 sanitary areas; and other 10 districts had only 59 cases in all. In the ealier period the deaths registered numbered 182, or 45 weekly, and yielded a case mortality of 15·6 per cent; but in the later period the registered deaths were 224, or 56 weekly, and the case mortality was 16·8 per cent. Thus not only has there been in London during the October-November period a heavier record of attacks of diphtheria than any chronicled since the close of 1895, but there has also been a heavier case fatality rate than in any period since May last. In the completed weeks that have since elapsed the registered deaths from diphtheria in London have been as follows: 46, 37, 63, and last week 52, the latter total being 5 in excess of the corrected decennial average for the corresponding week of the period 1887-96. Of the 52 deaths last week 7 belonged to Hackney, 7 to Lambeth, and 4 each to Kensington, St. Pancras, and Lewisham sanitary areas. Five of the deaths were of infants, 31 in all were of children under five years of age, and 3 were of persons aged over twenty years. The admissions to hospital during the week numbered 147, and 1056 cases of the disease were under isolation on Saturday last in London institutions. In the Outer Ring there were last week registered 15 deaths from diphtheria of which 6 occurred in the Edmonton union districts.

Appointments.

Successful Applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ALFORD, H. T. M., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Special Department for Diseases of the Ear at St. Thomas's Hospital.

BABINGTON, L.R.C.P., M.R.C.S., has been appointed House Surgeon to St. Thomas's Hospital.

BATEMAN, W. H., M.B., Ch.B. Vict., has been appointed a House Surgeon to the Manchester Royal Infirmary.

COBB, E. H., L.R.C.P., M.R.C.S., has been re-appointed Clinical Assistant in the Special Department for Diseases of the Skin at St. Thomas's Hospital.

COWBURN, A. D., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Special Department for Diseases of the Throat at St. Thomas's Hospital.

DAVIES, J. E. H., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the No. 6 Sanitary District of the Wrexham Union.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

"THE MICROBE OF DEATH."

To the Editors of THE LANCET.

SIRS,—The editor of *Pearson's Magazine* has drawn my attention to the criticism which appeared in THE LANCET of Nov. 20th of my story "The Microbe of Death." In this connexion I trust you will accord me the courtesy of your columns to make the following remarks. Your critic accuses me of (1) "gross plagiarism"; (2) ignorance of what I am writing about; and (3) giving "a grossly unfair description of the medical profession." 1. I have not only not read the book—"George de Barnwell"—from which I have "grossly plagiarised," but I fail to see the connexion instanced between my definition of "remorse—fear of detection"—and Barnwell's declaration "where there is no remorse crime cannot exist." 2. In the case of poisoning by anthrax through a wound "a pustule would almost certainly appear at the site of puncture.' "Almost certainly" admits the very possibility which is set forth as one of the proofs of my ignorance. 3. If by making a doctor kill a man "I give a grossly unfair description of the medical profession," would your critic, if I wrote a story of a woman who killed her own child accuse me of giving a grossly unfair description of maternity?

I am, Sirs, yours faithfully,

RUDOLPH DE CORDOVA.

Duke-street, Adelphi, W.C., Dec. 1st, 1897.

*** 1. We are quite ready to accept Mr. de Cordova's statement. If he will read "George de Barnwell," which is not a book but one of the "Novels by Eminent Hands" of Thackeray, he will we are sure see the similarity between the remarks we quoted. 2. We allow that in very rapid cases of death from anthrax there is no local manifestation. But it is exceedingly difficult to bring about such rapid death from a scratch and under the circumstances mentioned in the story impossible. Germs injected into a dying man, one actually dead within half an hour, would scarcely grow at all. The patient died between 5 and 6 A.M. and the post-mortem examination was made six and a half hours later. The body therefore could not have been swarming with bacilli, certainly not in sufficient number to kill a patient with the incredible rapidity mentioned—i.e., twenty-one hours—the means of inoculation having been the very slight scratch mentioned in the story. 3. We do not see the force of Mr. de Cordova's parallel. It is the deliberation and gloating over the crime to which we take exception.—ED. L.

STONE v. CEMENT.

To the Editors of THE LANCET.

SIRS,—Would you or any of your readers kindly favour me with an opinion as to the relative values of stone and cement work as to durability, &c. Some architects prefer in the building of churches, &c, stone, others cement petrified by a certain process based on chemical principles. These latter claim that their preparations last longer than stone and do not chip away as this does. One often notices in old abbeys, castles, &c., the cement work in a practically perfect condition while the neighbouring stones are crumbling away. Has the method of making such lasting cement ceased with our forefathers—is it a lost art? In the foregoing I refer particularly to facings, stucco work, &c., in buildings. An answer to this will be very highly esteemed by your constant reader.

I am, Sirs, yours faithfully,

Dec. 4th, 1897. S., M.D

P.S.—What book or authority on this subject would you recommend?

Enquirer.—If the vendor contracted to give an introduction of a certain sort and *this* can be proved and if the vendor failed to give the introduction and *this* also can be proved the payment of the balance of the purchase money might be legally resisted. We observe, however, that our correspondent says "the purchase of a practice involves a careful introduction." This is a matter of opinion and he will be unwise to take any steps without consulting a solicitor.

NASTINESS SUPREME.

IT is a notorious fact that the refreshments supplied at many of our public places of amusement are not of first-rate quality although high and even exorbitant prices are frequently charged. As the catering in public places is usually in the hands of a single firm there is no competition and advantage is taken of the fact to foist upon the public articles which are dear and nasty, but we sincerely trust that the practice which was disclosed in a recent case at the Kensington Petty Sessions is not by any means universal. It would appear that the well-known refreshment contractors, Messrs Spiers and Pond, caterers to the Victorian Exhibition, were summoned at the instigation of the Kensington Vestry for selling a sample of brandy and two samples of whisky which were not of the nature, substance, and quality of the article demanded. The defence set up was the extraordinary one that in one case a barmaid had emptied into the brandy and whisky decanters the remaining portion of a glass of brandy and water and also a portion of a glass of whisky and water left on the counter by customers. In the case of the other sample the barmaid had, in consequence of a complaint which had been made to her that the stock of the bar under her charge was unsatisfactory, put water into the syphon which supplied the tap from which the sample of whisky was purchased. The bench inflicted a penalty of £15. Apart from the fact that the spirits were adulterated the practice of emptying the leavings of customers' glasses into the vessels holding the spirits for public supply is a disgusting and filthy and dangerous one and the Vestry of Kensington deserve the unqualified thanks of the public for the action which they took.

Verbum Sap.—We doubt the preponderating political influence of the medical man and the social morality of employing it in the way suggested. We do not think a good citizen should make the particular wants of his class decide entirely where his vote should go.

"A TESTIMONIAL TO DR. JOHN T. ARLIDGE."

To the Editors of THE LANCET.

SIRS,—The insertion of the following list of further subscriptions to the testimonial to Dr. J. T. Arlidge will much oblige.

I am, Sirs, yours faithfully,

CHAS. F. MOORE.

10, Upper Merrion-street, Dublin, Dec. 7th, 1897.

	£	s.	d.
Rev. C. E. Waller	1	1	0
Prebendary Hutchinson	0	10	0
Miss Littledale	2	2	0
Dr. Peirce	2	2	0
Messrs. Gale and Co. ...	1	1	0
Rev. W. W. Tyson	2	2	0
Mr. John Strick	1	1	0
Mr. John Kendrick Wynne, M.D.	3	3	0

P.S.—Owing to my inability to decipher Mr. Thomas Fort's name, who is, M.R.C.S. Eng. and L.R.C.P. Edin., it appeared as "Dr. F." in THE LANCET of Dec. 4th.

M.D.—If there are public rumours the medical man has a right to correct them publicly. We are aware that such corrections are occasionally inserted on insufficient grounds or for too long a period or in somewhat unprofessional phraseology, but we do not understand our correspondent to allege anything of this sort against the advertisement he encloses.

Mr. W. H. Bull.—A very proper limitation is insisted upon and we see no evidence that it was not suggested by the medical man in all [illegible]

"THE ETHICS OF DEATH CERTIFICATION."

To the Editors of THE LANCET.

SIRS,—The following case which occurred in my practice the week before last may interest "Intimidad" and others of your readers. A fine healthy little boy, aged three years and three months, who had never had a day's illness in his life, complained of slight pain in his stomach and vomited at 11 P.M. on Wednesday, Nov. 24th. At 1 A.M. he was violently purged, the purging (which was painless) continuing the remainder of the night and following morning. He still had no pain, but seemed much exhausted. I saw him at 2.30 on Thursday afternoon. He was slightly cyanosed, the hands and feet were cold, the pulse was very weak (120 per minute), and the temperature was 101° F. There was no pain, tenderness, or swelling of the abdomen. Sore throat was not complained of, but the tonsils and fauces were congested and there was a uniform flushing of the skin. There was not then or subsequently any obstruction to the breathing and careful auscultation of the chest revealed nothing abnormal. The tongue was thickly coated with a yellow fur. I saw the child again at 10 P.M. when he was much the same, but the cutaneous flush was more marked as was also the congestion of the throat and the temperature was 103°. He had a bad night, the purging continuing but not severely, the stools being very green and sour-smelling but not very offensive. Next morning he was obviously worse. The feet and hands were cold, the lips and face were cyanosed, the flushing of the skin was gone, the throat was still slightly congested, the pupils were equal and contracted (that was their condition from the first), the tongue was clean and bright-red, and the temperature was 102°. The patient seemed very drowsy. At 1.30 he was rapidly becoming comatose; there were muscular twitchings and the temperature was 105°. At 4.30 Dr. Beattie, of Newcastle, saw him with me. He was then quite comatose, the pupils were equal but dilating, the pulse was quite imperceptible at the wrist, and the temperature was 105·6° in the axilla and 108° in the rectum. At 6 P.M. he died, the illness having lasted forty-three hours. Careful inquiry established beyond doubt that the child had had nothing but what others had partaken of and I had no hesitation in certifying that death was due to acute gastro-enteritis and septic absorption from the bowels.

I do not think "Intimidad" need have any qualms of conscience about his conduct. If he was satisfied that the gastritis in his case was due to natural causes he was quite justified in certifying. We are not, fortunately, called upon to certify the cause of the illness. If we were how many certificates should we have to refuse? In both his case and mine the symptoms might conceivably have been caused by some irritant poison, but having satisfied ourselves that they were not, what more was required? An inflammation of the lungs (not pneumonia) may be caused by exposure to cold or by the inhalation of an irritant gas, but we should not refuse to certify a death from that disease merely because of the latter possibility. And, again, in "Intimidad's" case the verdict of the coroner's jury would have depended entirely upon his evidence, so no possible good would have resulted from an inquest. As to a post-mortem examination, I doubt very much whether it would have thrown much light on either case. We could have demonstrated the absence of irritant poisons (supposing our opinions to be correct) and the presence of inflammatory lesions and so proved ourselves right. But the cause of those lesions, which is what we do not know, would most likely still remain obscure.

I am, Sirs, yours faithfully,

Wylam-on-Tyne, Dec. 6th, 1897. W. H. BISHOP.

Zeta.—It would appear from our correspondent's statement that he would not incur the penalty. The wording of the agreement might, however, indicate another construction.

A MEDICAL MAN IN BAD COMPANY.

THE following testimonial is printed in the *Dean Forest Mercury* of Feb. 3rd, 1897:—

"Mitcheldean, 25th October.

"Dear Sir,—I have found your Ointment most valuable as an application in Eczema and other skin diseases.

"J. ABELL, M.R.C.S."

The ointment thus eulogised is a preparation named "Marvello," which is prepared by the Royal Forest of Dean Remedy Co., and which, to quote another part of the advertisement,

"Gives immediate Relief and speedily Cures Burns, Scalds, Bruises, Rheumatism, Neuralgia, Bronchitis, Chilblains, Eczema, Croup, Catarrh, Sore Throat, Irritation, Humours, Boils, Erysipelas, &c."

Mr. J. Abell, M.R.C.S., who is a registered medical practitioner, should withdraw his public support of this quack remedy. If his name is being unjustifiably used he should insist on public reparation.

Consultant.—The wording of the deed of dissolution should have been more clear. In the absence of a definition of the word "consultant" the man who wrote the clause can alone say what he meant. We think it probable that A intended to see patients who came direct to him at an enhanced fee and not to confine himself to cases where he was called in by a professional brother; but if this was not made clear to B he has grounds for thinking otherwise.

THE VACCINATION AGE.

To the Editors of THE LANCET.

SIRS,—Since the Commissioners have recommended the extension of the present age (three months) to six months it appears to me highly desirable in view of the fact that legislative measures are likely to be made during the ensuing session to find out what public vaccinators think of this recommendation. I have no hesitation whatever in saying that my experience tells me that children under three months are, as a rule, in a far better condition to be vaccinated than those who have attained the age of six months. Those who have had to do with children know full well that the majority of infantile complaints occur after the first three months of the children's life. Beyond a little temporary attack of "red gum" children of that age really suffer from no other disorders. And moreover mothers believe in having their children vaccinated when they are under three months because they are so little trouble; in point of fact they (the children) sleep during the major portion of the twenty-four hours. The question (and it is a very important one in urban districts) arises whether the difficulties of tracing the abodes of the children will not be greatly increased if a period of six months is allowed for the performance of the operation. At the present time vaccination officers lose all trace of a considerable proportion of children and it is perfectly manifest that that proportion will increase enormously if any extension of time is allowed. I should like to add that I believe from an experience of five months in the use of calf lymph that no measure is so well calculated to do away with the unpopularity of the operation as vaccination with that lymph. Even more than the operation itself the taking matter from the children's arms was always a great source of irritation to the parents.

I am, Sirs, your obedient servant,

A PUBLIC VACCINATOR OF TWENTY YEARS' STANDING.

Dec. 6th, 1897.

*** Whilst giving every weight to our correspondent's argument we cannot but think the Commissioners' recommendation a wise one as tending especially to diminish the risks (slight and variable as they may be) which attend the practice of vaccination in the very young. After all, the raising of the age to six months is only doing for England and Wales what has long been the practice in Scotland, whereas in Germany—the best vaccinated country in the world—the limit for primary vaccination is two years. We would commend to our correspondent a careful study of the clauses 438 to 446 of the Final Report and also the references to this subject made by Dr. T. D. Acland in his exhaustive article on Vaccinia in the second volume of Clifford Allbutt's System of Medicine.—ED. L.

H. E. T.—There is room for the exercise of propriety in the printing o. such notices. The announcement seems to us to be a reasonable one, but our correspondent will be well advised not to make it in a type or style of vulgar conspicuousness.

One of Twenty-seven Years' Standing.—Yes, the decision is final. The terms of the notice will be found in our advertisement columns.

"OIL OF SANDAL WOOD."

MESSRS. W. J. BUSH AND CO., Limited, of Artillery-lane, Bishopsgate E.C., point out that a prejudice has been caused to both buyers and sellers of sandal wood oil by some chemists accepting as absolute the figures relating to its physical characteristics published by certain German chemists. To obviate this they wish to make known the results of their own observations together with those of other observers who have published their results from time to time. The rotation figures in these observations are for monochromatic (D) light, but in the other cases the source of light is not stated; the figures for ordinary light (transition tint) would with most substances be considerably higher. It is evident from the results recorded that English drawn oil from East Indian sandal wood may vary in density from 0·970 to over 0·980, and it would appear that, as might be expected, the German distilled oil varies to the same extent. The rotation also may vary from 16° to 20°, and it is not advisable to fix narrower limits than these for density and rotation. They agree with previous observers as to the solubility in 70 per cent. alcohol, all the oils distilled by themselves having been found to be readily soluble in less than five parts by volume and spirit at 20° C.

Starboard.—We do not know what official view the General Medical Council might take, but we consider that the circulation of a medical man's name in such a way is distinctly inadvisable.

WANTED A SCHOOL.

To the Editors of THE LANCET.

SIRS,—Can any of your readers inform me of a charitable institution where a boy, aged eight years, and a complete cripple can be received for educational purposes? He lives in the country, his parents are poor, and the nearest school is some miles away.

I am, Sirs, yours faithfully,

123, Stamford-hill, N., Dec. 3rd, 1897. D. MOWAT.

"A FAMOUS PARISIAN LADY SPECIALIST."

To the Editors of THE LANCET.

SIRS,—Who was Dr. Marion Sims? I, a layman, don't know. But I happen to have seen the other day a circular bearing the name of a chemist not unknown describing something invented by the *late Dr. Marion Sims, a famous Parisian lady specialist.* I once heard of a man who took Marion Crawford down to dinner and found her a most charming and accomplished lady. If this is a parallel case it might amuse your readers to hear of it.

I am, Sirs, yours truly,

Dec. 7th, 1897. A BARRISTER.

Dr. Arthur E. Larking.—We are not responsible for the opinions of our correspondents.

A QUESTION FOR MUTUAL SETTLEMENT.

M.B. Vict. writes: "A is a resident medical officer in a workhouse hospital. B is a consulting medical officer to the same and attends every morning and at such other times as his services are required. If during B's absence A diagnoses or admits any case of infectious disease A at once notifies them to the local authority and claims the fee. B says that A has no right to notify these cases, but that A ought to report them to B, and B will notify them. Is not A quite correct in the course he is pursuing as he is a registered practitioner as much as B is?"

*** It would be a great pity that so trivial a matter should break the harmony that should exist between two gentlemen standing in close professional relation towards each other. There cannot be a right or a wrong in the matter, all that is wanted is a decision, but it would be idle to give a decision, which must be to some extent capricious, unless the arbitrator knew that both gentlemen were prepared to abide by it.—ED. L.

Selhurst.—The best course would be to trace the falsehood to some one and ask the individual to make public retractation of his error. Our correspondent might advertise a correction once or twice, but this proceeding is open to abuse and does not dispel the old rumours.

A Fellow of the Society of Medical Officers of Health.—We shall be happy to read anything that is sent us in proof of the desirability of an independent investigation being made.

A PROTEST.

To the Editors of THE LANCET.

SIRS,—I was recently elected as a resident medical officer to an infirmary in England. Immediately after the election I learned on inquiring that I should be expected to share a sitting-room with a lady doctor, who is one of the three residents to the institution. As this was practically the only sitting-room accommodation which the committee could provide—the alternative being the board-room, which serves also for a secretary's office—I felt bound on principle to resign the post. I should like to know whether such an arrangement as this exists in any other English hospital and if not whether it appears to your readers as one which is likely to become popular. As far as I know the experiment has never before been put to the test in the infirmary in question and as the post is still vacant it remains for someone else to establish in hospital life a custon which is presumably new and one which surely is a little "before the times."

I am, Sirs, yours faithfully,

Dec. 3rd, 1897. PUDOR.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received: *Manchester Guardian, Bedford Standard, East Anglian Daily Times, Newcastle Leader, Yorkshire Herald, Glasgow Herald, Birmingham Post, Pioneer Mail, Times of India, Hereford Times, Somerset County Gazette, Dundee Advertiser, Liverpool Daily Post, Architect, Builder, North British Daily Mail, Norwich Mercury, Royal Cornwall Gazette, Newbury Weekly News, Keighley News, Science Siftings, Leeds Mercury, Kensington News, Cambridge Independent Press, Bury Guardian, Bolton Chronicle, Mirfield Reporter, Sheffield Telegraph, Surrey Mirror, Wolverhampton Chronicle, Newport Advertiser, Bridgwater Independent, Yorkshire Post, Heckmondwike Reporter, Bristol Mercury, Chester Chronicle, Herald of Wales, Waterford Chronicle, Kidderminster Shuttle, Sussex Daily News, Sanitary Record, Northern Chronicle, Mining Journal, Public Health, Engineer, Local Government Chronicle, Reading Mercury, City Press, Hertfordshire Mercury, Local Government Journal, Lancaster Observer, Guy's Hospital Gazette, Welshman (Carmarthen), Surrey Advertiser, Weekly Free Press and Aberdeen Herald, West Middlesex Herald, Newport Pagnell Gazette, Prescot Reporter, &c., &c.*

Christmas Presents

FOR

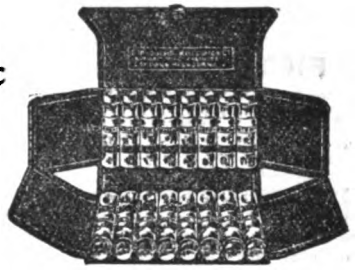
MEDICAL MEN.

TRADE MARK 'Tabloid' BRAND

Medicine & Hypodermic Cases

No. 16.

'TABLOID' MEDICINE CASE.



In black or olive green Levant morocco. Outside measurements, 8½ × 3¾ × 1¼ in. Contains eight ½-oz. and six 1-dr. vials fitted with 'Tabloid' Compressed Drugs, from 19/-.

Also supplied in "natural" tint crocodile.

SILVER HYPODERMIC 'TABLOID' CASE.

Solid silver, gilt lined. Fitted complete with solid silver syringe, platino-iridium needles, fourteen tubes of 'Tabloid' Hypodermic Drugs, etc., £10 10s.

No. 17.

'TABLOID' MEDICINE CASE.

In calf. Outside measurement, 7 × 3½ × 2 in. Contains sixteen ½-oz. vials fitted with 'Tabloid' Compressed Drugs, from 22/-.

Also supplied in cow hide from 24/-, and in olive green Levant morocco from 23/- each.

No. 7.

'TABLOID' HYPODERMIC POCKET CASES.

Nos. 7 and 21	12/6 ;	No. 30,	14/- each
do. in brown or green seal	18/- ;	,,	19/- ,,
do. in crushed morocco	19/- ;	,,	20/- ,,
do. in brown or green crocodile	20/- ;	,,	21/- ,,

No. 30.

No. 24.

'TABLOID' EMERGENCY CASE.

A complete 'tabloid' equipment of hypodermic and other drugs suitable for emergencies, hypodermic syringe, etc., 24/- each.

In brown or green seal .. .. 32/- each
,, ,, crocodile .. 40/- ,,

In addition to those illustrated above, the following will be found handsome cases for presentation. All are fitted with 'Tabloid' Compressed Drugs, and, in the Hypodermic Cases, syringes, needles, and other accessories are included. Further illustrations and particulars will be sent on request. Special designs are made to order.

'TABLOID' MEDICINE CASES.

No. 16A.—In Black Morocco... ...	from	13/- each

NEPENTHE.

The Safest and Best Preparation of Opium.

PRODUCES NEITHER HEADACHE, SICKNESS, NOR CONSTIPATION.

PREPARED EXCLUSIVELY FROM OPIUM.

THE BEST FIFTY YEARS AGO.

"7, GROSVENOR STREET,
"GROSVENOR SQUARE.
"October, 1847.

"Sir,—

"Having for the last eight or nine years prescribed your 'Anodyne Tincture' in all cases requiring such a remedy, I am induced to speak of its effects both as a Sedative and an Anodyne in the highest terms. The sleep produced by it is more refreshing and more allied to natural sleep than that arising from the use of any other narcotic with which I am acquainted.

"One of its greatest advantages, however, is that it does not act as an astringent according to my experience, nor does it produce any of the unpleasant effects which usually accompany the use of this class of medicine.

"I remain, Sir,
"Your obedient servant.
"S. M——, M.R.C.S."

[CERTIFICATE.]

"*Nepenthe, or Anodyne Tincture.*

"I have had many opportunities of witnessing the very excellent effects of 'Anodyne Tincture' in the numerous affections where an opiate is deemed advisable. It gives no headache, does not interfere with the proper action of the bowels, it rather promotes than diminishes appetite, and gives tranquilising and refreshing sleep in many very painful nervous affections.

"With such strong recommendations I consider it an invaluable preparation of opium. "C—— G——, M.D.,
"Physician to Bath Institution for Diseases of the Chest, &c.
"Bath, Sept. 24th, 1849."

THE BEST TO-DAY.

"17th June, 1895.

"DEAR SIRS,—

"I have used your preparation 'Nepenthe' for a number of years in cases of insomnia connected with insanity, and have always found it above all other anodynes the 'King of Narcotics.' I don't think I should be doing you justice if I did not report to you on its marvellous efficacy. I have found it always produce hours of peaceful sleep, and to be unattended by any bad results. Patients suffering from melancholia with accompanying insomnia under my care have taken it every night for years without one bad symptom. I never find thirst, dryness of the tongue, or constipation result from its use, and I view it as the most valuable remedy we possess for allaying brain irritation, and producing peaceful and healthy sleep. I have thoroughly tested all the various remedies usually given for the relief of some of the troublesome phases of mental disease, and can safely say that none are so good or reliable as 'Nepenthe.' It has all the good properties of opium without any of its drawbacks.

"I am, dear Sirs,
"Yours truly,
"————,
"L.R.C.S.Edin., L.M., L.S.A., &c.,
"Mem. Med. Psycholog. Assoc."

N.B.—**Nepenthe is registered under the Trade Marks Act**, and every bottle bears a facsimile of FERRIS Co.'s Signature pasted over the cork.

NEPENTHE is sent out in 2-oz., 4-oz., 8-oz., and 16-oz. Bottles, bearing a label in white letters upon a green ground, and is stocked by all the leading Wholesale Druggists and Patent Medicine Houses.

We prepare also **DOUBLE STRENGTH NEPENTHE** (red label), and **GLYCEROLE OF NEPENTHE** for Hypodermic Injection.

ABSTRACT OF

The Bradshaw Lecture

ON THE

CORRECTION OF CERTAIN DEFORMITIES BY OPERATIVE MEASURES UPON BONES.

Delivered before the Royal College of Surgeons of England on Dec. 8th, 1897,

BY ALFRED WILLETT, F.R.C.S. ENG.,
SURGEON TO ST. BARTHOLOMEW'S HOSPITAL.

MR. PRESIDENT AND GENTLEMEN,—The subject I have chosen for this year's Bradshaw Lecture is "The Correction of Certain Deformities by Operative Measures upon Bones."

To Mr. Wm Adams, of orthopædic surgery fame, must be ascribed the distinction of first placing before the profession—certainly in this country—a definite and carefully matured plan for correcting faulty position in cases of synostosis at the hip joint, for which he proposed to saw through the neck of the femur. Mr. Adams called his operation—which by the way was performed for the first time on Dec. 1st, 1869—subcutaneous osteotomy, since he operated upon the lines of subcutaneous tenotomy, making an incision only just large enough to admit of the introduction of a fine saw he had devised, then sawing in great part through the neck of the femur, and finally wrenching forcibly, he in this way fractured the bone. He instantly closed the wound, and all through the operation carefully excluded the entrance of air. Adams's operation was introduced before the days of antiseptic surgery and although in his cases I believe suppuration rarely occurred other surgeons who followed his teaching were not so fortunate, suppuration following in not a few instances; whilst even Mr. Adams himself, Mr. John Croft, and I had each to record a fatal result. At the time Mr. Adams claimed the highest surgical importance for the subcutaneous character of his operation as introducing a new feature and a wider scope for the principles of subcutaneous surgery—for by open wounds other surgeons, both in this country and in the United States, had divided bones, taking away even wedge-shaped portions in close proximity to joints for the correction of deformities, the result of synostosis in faulty position after arthritic disease. I only allude to the importance then claimed for the subcutaneous principle in Adams's operation to say how entirely it has vanished under the universal acceptance of the Listerian law of asepsis in operative surgery.

Osteotomy has since been performed in many similar deformities such as faulty position after fracture, the division of, or removal of wedge-shaped portions from, curved rachitic bones and the like. In 1879 Prof. Macewen, of Glasgow, brought before the profession a new method of dividing bones by mallet and chisel, applying it specially to the correction of knock knee. But with the advent of antiseptic surgery more extensive operations by open wounds of sufficient magnitude for the necessary manipulation have been introduced, so that now, with but little risk to life or limb, operative measures are adopted for the radical treatment of a large number of deformities. Yet another measure must be mentioned—an operation having for its object the production of a simple fracture by a powerful specially contrived apparatus such as was a few years since introduced by the late Dr. Grattan, of Cork. He gave the name "osteoclasia" to the operation and of "osteoclast" to the instrument. Rapidity of action in an osteoclast is essential; sudden impact also seems necessary to make a bone crack across as well as to avoid seriously damaging the soft parts by continuous pressure. In all these points Thomas's osteoclast has the advantage over Grattan's. Osteotomy is the most reliable operation for deformities involving long bones and is the one I invariably select for patients over the age of fourteen years. Its performance is characterised by great precision; it is most effective in accomplishing the desired object and has but very rarely been associated with disaster of any sort. Whilst, however, its risk in children is almost *nil*, I must confess that I undertake Macewen's operation with some misgivings in young adolescents who are growing rapidly and whose bones are very vascular, as it is in such patients as these I have seen osteomyelitis and necrosis supervene twice, whilst not infrequently a sharp rise in temperature has caused anxiety for a few days. Personally, as between saw and chisel I prefer, where choice may be said to exist, the chisel.

[Mr. Willett here stated that he considered it very important not to close the osteotomy wound so that no tension might result from the accumulation of blood.]

One objection taken against osteoclasia is that the operator cannot ensure the line of fracture being at a given level with the exactness that is attained in osteotomy, but I must say I regard it as immaterial to the success of the operation whether the fracture takes place an inch higher or lower in the bone, for after both operations a fining down of the irregularities in outline may be confidently expected to follow. And by the growth of the bone the original situation of the fracture is altered. I regard the age of thirteen or fourteen years as about the highest limit at which osteoclasia should be practised. Above this age there must be, owing to the strength of resistance in the bones of the thigh and leg, so much risk of lacerating the soft parts that osteotomy is preferable. But as acquired deformities are mostly seen under this age limit and as genu valgum and rachitic curved tibiæ form a large proportion of the deformities coming under treatment it follows that I have adopted osteoclasia very generally at St. Bartholomew's Hospital. I should add that even in young subjects the osteoclast occasionally fails. This seems to be due to the yielding condition of the bones in the primary stage of rachitis rather than to any defect in the osteoclast. Only once have I seen any skin lesion beyond simple bruising occur. In the comparatively few instances where I have subsequently performed osteotomy when osteoclasia has failed, the operation has been carried through just as satisfactorily and completely as if no previous attempt had been made to fracture the bone.

As the correction of deformities in the upper extremity is so seldom called for, except for faulty position after fracture, I propose only to take into consideration the application of the operations I have mentioned to the deformities of the lower extremities. Upon investigation I find I have performed 634 operations on 383 patients. The proceedings have been as follows: viz:—1. For deformities due to ankylosis at the hip 11 Adams's and 20 Gant's operations, making a total of 31 operations performed on 28 patients; 2. For knock-knee and allied deformities 232 Macewen's operations were performed on 137 patients, 159 osteoclasia operations on 83 patients, and 21 Reeve-Ogston operations on 16 patients, making a total of 412 operations on 236 patients. 3. For bow-leg 40 osteotomy operations were performed on 32 patients, 105 osteoclasia operations on 55 patients, total 145 operations on 87 patients. 4. For inveterate club-foot 23 astragalectomy operations (tarsotomy and tarsectomy) were performed on 14 patients. 5. For hallux valgus and its allied conditions 14 operations were performed on 9 patients. 6. For deformities resulting from fractures of long bones 9 operations were performed on 9 patients. There have been 2 deaths—1 after Adams's and 1 after Macewen's osteotomy.

The most common deformity in ankylosis at the hip-joint is flexion, inversion, and adduction; this induces as a secondary result lordosis and lateral tilting of the pelvis. A less frequent but still well recognised deformity is outward rotation with more or less of abduction and perhaps with flexion. Now as to the nature of the uniting bond. The cases may be classified as follows: (1) there may be simply synostosis of the head of the femur to the acetabulum, occasioned by some very acute inflammatory affection, most frequently of an infective type, such, for example, as gonorrhœal rheumatism; or (2) the ankylosis, being also bony in character, may be very much more widely diffused, as is commonly seen in tuberculous disease of the hip-joint, where caries has extensively affected the bones on either side of the articulation; and (3) the ankylosis may be firm, close, and extensive, but the bond of union remain fibrous. This condition may result from more chronic forms of rheumatism and tuberculosis, where the disease remains limited mainly to the synovial membrane and fibrous capsule of the joint with, later, fibroid degeneration of the cartilages.

If we place the first and probably most of the third of these classes into one group and regard them with Mr. Adams as the rheumatic type in which the greater trochanter stands out prominently, indicating the existence of a healthy neck of the femur with as a rule absence of old abscess scars, and

Digitized by Google

in which also there is an entire absence of bosses of new bone around the hip-joint, we have the cases of deformity for which Adams's operation was devised and for which its author has expressly limited its employment. In the second class, called by way of contrast the tuberculous, where scarring and production of new bone with thickening and flattening of the trochanter are present, we have on the other hand the cases which Mr. Adams emphatically pronounced to be unsuitable for his operation. It was for this class, forming by far the larger proportion of cases of deformity after hip-joint disease, that Mr. Gant devised sub-trochanteric osteotomy. Thus the aim of both surgeons was to divide the femur where it was healthy, and since Adams and Gant devised their operations for quite distinct conditions there is in practice seldom any difficulty in deciding which operation should be performed.

[Mr. Willett does not consider it necessary to attempt to procure a false joint after osteotomy of the neck of the femur unless synostosis of the joints of both sides is present, but in these cases it is absolutely necessary to procure at least one false joint.]

One other point which I desire to touch upon is the line or position in which the bone should be placed or set, after the completion of either Adams's or Gant's operation. I use a double Thomas's hip-joint splint in these operation cases. Every surgeon knows, if after hip disease adduction of the thigh forms one element in the deformity, that then the apparent shortening of the limb will be greater than the real; on the other hand, if the thigh be abducted, the difference is the other way, either the apparent shortening is less than the real, or apparent lengthening is found. Well, if on measuring the two limbs before operation I find actual shortening exists then in setting the limb after osteotomy I place it in the abducted position, the result being that when union has taken place that side of the pelvis is permanently tilted downwards; the apparent shortening is correspondingly lessened and sometimes so completely as to make it unnecessary to add a cork sole to the patient's boot.

Passing from this subject I turn to those deformities at the knee of which knock-knee forms the most common example. It is, I think, unfortunate that there is no generally accepted rule for estimating the extent of the deformity in knock-knee—I mean in relation to the amount of abduction of the leg.

The angle which I am accustomed to take for recording the amount of deformity in a case of knock-knee is the one formed at the outer aspect of the joint by the meeting of two lines, the one drawn downwards from the great trochanter to the external tuberosity of the tibia, passing over the outer surface of the external condyle, and the other upwards from the external malleolus to the outer surface of the external tuberosity of the tibia.

Assuming that an operation is necessary the choice seems to me to lie between (*a*) Macewen's transverse supra-condyloid osteotomy; (*b*) an osteotomy detaching the internal condyle by the Reeve-Ogston method; and (*c*) osteoclasia. First, then, for all patients under the age of thirteen in whom the recording angle is not less than 120° I perform osteoclasia; about four-fifths of all cases fall into this category. In cases above this age, presumably patients whose femora are too dense to be broken by the osteoclast, I perform transverse supra-condyloid osteotomy. There remain the cases in which the recording angle is less than about 120°, in other words more nearly approaching a right angle.

[Mr. Willett then mentioned that in these the skin on the outer side might be so very tightly stretched after Macewen's operation as to make it impossible to correct the deformity, and continued:]

I now make it a rule in all such cases to treat them by the Reeve-Ogston operation in the first place, and although in one or two instances I have had to supplement this operation by a supra-condyloid osteotomy, yet in nearly all instances the Reeve-Ogston operation has proved quite adequate for the complete correction of the deformity.

Early in my lecture I implied that for rickety deformities of the bones of the leg in young patients the operation I am in the habit of performing is osteoclasia and I am confident that my success in correcting deformities in these cases is quite as good as, and I am inclined to think better than, by osteotomy either with or without removal of a portion of bone, while the convalescence of the patient is greatly expedited.

As rickety bending and bowing of the legs predominates in quite young subjects I have in recent years had but few occasions for performing osteotomy. I will, however, take the opportunity of saying that I am not in favour of removing wedge-shaped portions of the tibia in correcting the severer forms of this deformity partly because union is delayed by this step but chiefly because I have not found it necessary, for by sawing in an oblique line over the convexity and completing the division of the bone with the chisel I am enabled to slide the lower fragment upwards and by this manœuvre to bring the leg straight.

At this point it will, I think, be convenient to offer a few remarks upon the operative treatment of badly united fractures. In fractures of the long bones, usually from some peculiar incident in the circumstances of the patient's treatment, union may occur in wholly abnormal positions and cause very marked conditions of deformity. In cases like these re-fracture permitting reduction into proper position is imperatively required; if the accident has been tolerably recent this may be easy, occasionally I have used the osteoclast. Should all efforts fail osteotomy is the only resource left, and I have obtained very satisfactory results by this operation. I would just mention that it is very essential for its success that the fragments should be disengaged very thoroughly, and after careful adjustment I have generally found it necessary to employ very much more extension-weight than in ordinary simple fractures to ensure full length being maintained; in one instance I used as much as thirty pounds of shot in a canister. The ultimate results not only as regards union but position are, in my experience, extremely satisfactory, although constant supervision is needed to ensure success.

The next deformity I propose to discuss is the treatment of inveterate club-foot. I would premise that in my opinion radical operations for congenital club-foot are only justified either by the neglect of treatment by tenotomy in early childhood or where, relapse having occurred, a condition appropriately termed inveterate talipes exists. Indeed, I desire to express the strong feeling I entertain that this affection is not only curable in infants by appropriate treatment, but that this result ought to be obtained practically within the first year of life. But I hold equally strongly that when this condition is established a radical correction of the deformity is called for and that an operation should be performed entailing either the removal of a single tarsal bone or the removal of parts of several of these bones.

Of several operations which might be named, the one which I have come to regard as the best is astragalectomy. Anyone who studies the condition of the bones of the foot in a case of inveterate talipes cannot fail to note a special abnormality in the astragalus which, I think, has a determining influence in maintaining much of the deformity in the foot anterior to this bone. This peculiar defect lies in the inward curving at its neck, for from this circumstance it follows that the scaphoid, cuneiform, and indeed all the bones in advance of it are directed inwards. Again, the astragalus is the connecting bone between the tibia and fibula above and the os calcis with other bones of the foot below; hence it will be found that when the astragalus has been removed the foot can readily be placed in a natural position. A very marked instance of the superiority of this operation was seen in my wards at St. Bartholomew's Hospital some years ago. A boy about ten years of age was the subject of congenital double talipes equino-varus. In one foot, the left, the operation of tarsectomy had been performed at another hospital; the usual wedge-shaped piece had been removed; nevertheless the deformity had not been materially altered, the foot was still turned inwards and upwards and the boy still walked upon the outer surfaces of his feet. I performed the operation of astragalectomy on the other foot—the right—which came at once into good position. The result of this operation was so satisfactory that subsequently I performed the same operation upon the left foot; the ultimate result in both instances being that the patient walked well on the soles of both feet, but the right foot—that from which the astragalus alone had been removed—proved the stronger and better foot, the other being stunted and more rigid. I have in one or two instances after the operation of astragalectomy found it necessary to perform tarsotomy to correct the inward turning of the distal part of the foot.

Of other operations which have been suggested, such as the division of the neck of the astragalus—the division of all the ligaments on the inner side of the ankle or forcible rectification by crushing up the tarsus collectively—one and all have seemed to me proceedings either so much more

Digitized by Google

severe than the removal of the astragalus or wanting the advantages gained by that operation.

There is one other group of deformities on which I would wish to offer a few brief remarks—it comprises hallux valgus, hallux flexus, and hallux rigidus. These conditions have been discussed very thoroughly by Mr. Davies-Colley in the Guy's Hospital Reports and by Mr. Walsham in his work on "Deformities of the Foot." Time would not permit me nor, in view of the writings of these two surgeons, is it necessary to treat of the pathology and etiology of this deformity. The operation which I have invariably performed is that recommended by my colleague Mr. Walsham and it consists in the removal by an open linear incision over the internal surface of the metatarso-phalangeal joint of the whole of the head of the first metatarsal bone. Much care is needed to place the toe in line with the inner border of the foot as well as to maintain it in this position for a month or six weeks in order to obviate relapse, whilst passive movements should be commenced in a fortnight from the operation. I perform the same operation in hallux flexus and rigidus.

With this deformity of the great toe I, not inappropriately, come to the end of my lecture, not that I would for a moment pretend to have exhausted the subject of the correction of deformities by operative measures upon bones, only that I have dealt with those of them with which I am fairly familiar, having in the thirty-two years during which I have been on the surgical staff of St. Bartholomew's Hospital had considerable clinical experience in this field of operative surgery. I hope that what I have ventured to put before you has not seemed fragmentary or disconnected. I return you, Mr. President and gentlemen, my most cordial thanks for the attention you have bestowed upon me.

Two Lectures
ON
URINARY FEVER.

Delivered at the London Hospital on July 7th, 1897,

BY C. MANSELL MOULLIN, M.D. OXON., F.R.C.S.ENG,

SURGEON TO, AND LECTURER ON SURGERY AT, THE LONDON HOSPITAL; EXAMINER IN SURGERY AT THE UNIVERSITY OF OXFORD.

LECTURE I.

GENTLEMEN,—There have been several cases in our wards recently of what is commonly spoken of as urinary fever. As some of them have presented symptoms of an unusual character and as many of them have proved of especial interest I propose to group them together and to point out to you what pathological factors are common to them all and how far we are justified in using a term such as urinary fever—fever, that is to say, caused in some way by the normal constituents of the urine.

CASE 1.—The first case occurred a few months ago, but it was of so striking a character that it is scarcely likely to have faded from the recollection of those among you who happened to see it. The patient was a young girl in Sophia Ward. All her life she had suffered from symptoms of calculous pyonephrosis. Six weeks before I had removed from the right kidney a large branching calculus with several smaller ones, some of which were certainly fragments broken off. The operation was a severe one and her recovery was slow. Rigors, concerning which I shall have something to say later, occurred on several occasions. But by degrees the wound contracted to a sinus, the amount of discharge diminished, and the temperature fell to normal. The pain however did not disappear. That one tell-tale spot opposite the tip of the eleventh rib persisted. The slightest percussion there caused a sharp stab of pain and it was evident that something had been left behind. Accordingly I explored the kidney a second time. The first operation was one of considerable difficulty. The patient's chest was very long, so that the lower ribs almost touched the pelvis; the kidney was completely covered by the ribs and was very moveable and a great deal of manipulation was required to extract the stone. The second operation was as simple as such an operation can be. The kidney was fixed and drawn much nearer to the surface by the cicatricial tissue that had formed around it. A sinus led down into the pelvis. All that was required was to dilate this sinus and introduce the finger into it. A small calculus was detected almost at once lying in the upper part of the pelvis in one of the calyces and extracted without difficulty. The operation lasted a very short time; the patient was not chilled in the least and there did not appear to be any reason why shock should be severe. In the evening it was noted that the extremities were warm and there was no fall in the temperature. The thermometer in the axilla marked 98° F. The next morning it was 101° and in the afternoon it had fallen again to 99°. But the face was dusky and the pulse was quick and running; a diffuse erythema had made its appearance over the lower part of the body and the thighs, and the patient died in the course of the evening within thirty hours of the operation. There was no suppression of urine or vomiting.

At the post-mortem examination all the viscera were more or less congested. The opposite kidney was healthy and sufficiently large. There was no evidence of peritonitis and there was no hæmorrhage or thrombosis. The patient retained a certain degree of consciousness almost to the last, but lay perfectly quiet with eyes half closed, scarcely answering when spoken to and taking no notice of anything that was going on around. The condition, in short, was such as is sometimes seen in very severe cases of acute suppurative osteomyelitis—cases that prove fatal before any secondary pyæmic symptoms such as pericarditis have had time to develop.

Such cases are fortunately of rare occurrence. A few of a similar character have been recorded at various times by other surgeons and they have been regarded by most as the result of shock. With this opinion, however, I am quite unable to agree. So far as I understand shock the characteristic symptoms are entirely wanting. Shock I admit is often very severe after operations upon the urinary organs and especially upon the kidneys. I have been told by Dr. Hewitt that he has several times known the pulse to fail at the moment that the ligature was tightened around the pedicle in performing nephrectomy. The operation is a long one. The wound is of considerable depth. The semilunar ganglion is in close proximity, and the nerves of the renal plexus are often included in the loop thrown around the vessels But the symptoms in the case that I have described to you were totally different from those of shock. In shock the temperature always falls. The extremities grow colder and colder. The face and lips are white and the forehead is covered with perspiration. The eyes are sunken and surrounded by dusky rims. The nose is pinched and the secretion of urine is either stopped altogether or falls very far short of the normal. I cannot, therefore, regard this as a case of shock. On the other hand there can be no question that septic poisons were present in the wound, that they were of the most virulent character, and that there was every facility for their absorption. The mixture of pus and urine that filled the pelvis of the kidney and overflowed into the sinus was full of micro-organisms. They consisted for the most part of staphylococci and a bacillus which agreed with the bacillus coli in its mode of growth upon potato and gelatin and the rapidity with which it coagulated milk. As usual when this bacillus is present in any numbers the odour was decidedly fæcal. These organisms must have been growing in the pelvis of the kidney in very favourable circumstances for some considerable time. The fluid therefore that filled it certainly contained some, probably a large amount, of their toxic products. And the operation was one that might very easily have resulted in forcing some of these products into the open ends of the torn vessels. Nor can there be any doubt as to the virulent character of these toxins. Numerous experiments upon animals have been performed abroad by Melchior, Gilbert, and others and they have shown conclusively that the most minute quantity injected into the circulation gives rise to fever, with loss of appetite, apathy, and diarrhœa, and that a quantity only slightly larger will cause dyspnœa, convulsions, and fatal collapse. Sometimes there is high fever, sometimes a temperature below normal, and mixed toxins such as were present in this case are often much more poisonous than would be expected from the effects they produce when acting separately. All the conditions, in short, for the production of acute septic poisoning were present in this case and I regard it as an instance not of shock or urinary fever, but of acute septic intoxication due

Digitized by Google

to the sudden entrance into the circulation of an overwhelming dose of mixed toxins at a time when it can easily be imagined the kidneys were not working at their best. The germs themselves may have entered too; it may have been a case of septic infection as well as of septic intoxication; but the symptoms set in with such rapidity and intensity that they could scarcely have been caused in this way. There was no time for incubation.

CASE 2.—The second case to which I wish to call your attention is one that occurred only a few days ago. The patient was a man, in other respects healthy, who was suffering from stricture of the urethra and upon whom internal urethrotomy was performed. As in most cases of stricture that present themselves for operation there was a purulent discharge from the urethra and this, as usual, contained numbers of the bacillus coli with other organisms. The urine, too, contained the bacillus coli, as was shown by the appearance of the cultures that were grown from the sediment upon potato and gelatin. A few hours after the operation, shortly after passing urine, he was suddenly seized with a violent shivering fit. The temperature rose to 104° F. There was a sensation of the most intense cold so that the teeth chattered and the limbs quivered until the bed shook. This was followed by burning heat, and in a few minutes this, in its turn, gave way to profuse perspiration. The next day he was quite well and no ill result of any kind followed.

Such cases are common. You must have seen many of them, as stricture of the urethra is so frequent here. Sometimes there is more than one rigor, but whether there is one or more than one provided there is no serious renal disease and the temperature soon falls to normal there is no occasion for alarm. These rigors are typical instances of what it is customary to speak of as urinary fever. They are due, however, not to the absorption of any normal constituent of the urine or to any nerve irritation, but, like the collapse in the first case that I described to you, to the sudden entrance into the circulation of some of the products of the organisms (and especially of the bacillus coli) growing in the urine or on the walls of the urinary passages. They are examples, in other words, of septic poisoning and should not be called urinary fever at all. Normal urine, if it is absorbed or injected into the circulation in sufficient quantity, will give rise to symptoms of poisoning, but not to such as were present in either of these cases.

I am aware that this is not the view that is generally received. The current explanation is that these rigors, as they may certainly occur without organic disease of the kidneys, are due to some transitory or functional affection caused by the passage of an instrument through the deep part of the urethra. Now it is impossible to disprove so vague a statement as this. It rests solely upon authority, not upon facts. Even if it is conceded that renal congestion may be caused by the passage of catheters through the deep urethra (and this is certainly not a common occurrence) there is no proof that the congestion can cause a rigor such as these. On the other hand, there is no difficulty in showing that septic organisms are always present in these cases, that the toxins they form are capable of causing these symptoms and even worse ones, and that the frequency with which these rigors occur is proportionate to the facilities that are offered for the absorption of the toxins. Normal urine is sterile; it does not contain any organisms. Nor are there, as a rule, any pathogenic organisms in the deep part of the male urethra so long as it is healthy. In stricture cases, however, and especially in those that require operation, it is absolutely different. There is always a certain degree of urethritis and generally of cystitis, and whenever you meet with either of these the bacillus coli or some other equally septic organism is invariably present. The septic organisms are the cause of the inflammation and inflammation of this character never occurs without them. I have examined the urine in twenty consecutive cases of cystitis (excluding tuberculous ones) and the bacillus coli was certainly present in eighteen and probably in the other two. There can be no question that septic organisms are invariably present in the urethra and in the urine in cases of stricture attended by the slightest degree of urethritis. Nor is there a doubt as to the intensely virulent quality of the toxins that are produced by the bacillus coli. A good deal depends upon the source whence the culture is taken (that which comes from a perfectly healthy intestine has been shown to be not nearly so powerful as one taken from a case of diarrhœa; and this in its turn cannot be compared with a culture from a case of English cholera), and still more upon the conditions under which it is grown. But experiments performed abroad have shown conclusively that a perfectly infinitesimal quantity if injected into the veins or the peritoneal cavity of a rabbit is sufficiently active to cause prostration and even death.

But this is not all. If you inquire into the conditions under which these rigors occur you will find that not only is a septic poison present in every case, but that rigors are common in proportion to the facilities that are offered for its absorption. The mucous membrane that lines the urethra is very different in this respect from that of the bladder. Even when it is uninjured, when there is no wound or recent abrasion of the surface, it absorbs everything that is brought into contact with it. Cocaine, for example, is taken up by it with the greatest readiness. In those who are susceptible to its influence I have several times known an injection of cocaine into the urethra followed by definite symptoms of poisoning within a minute. When there is a recent wound absorption is easier still. And every time the urine passes down the urethra there is a very considerable rise in pressure. Given these facilities and the presence on the surface of the mucous membrane of septic organisms producing a virulent poison, is it wonderful that some of it is absorbed? The clinical circumstances under which urethral rigors occur afford further and even more direct evidence of this. The most frequent of all causes is an operation upon the deep part of the male urethra. Those performed upon the penile part are rarely followed by them and they never occur after such a proceeding as division of the meatus. Women are not exempt from them, but for obvious reasons rigors are much more rare in them. Rigors may be caused by simple exploration with a catheter or dilatation or internal urethrotomy. External urethrotomy is much less liable to be followed by them than internal. And I have many times known that while every attempt at passing a catheter through a stricture gave rise to a rigor, free and clean division of the obstructing ring put a stop to them once and for all. Tying a catheter into the urethra is one of the most effectual methods of preventing the occurrence of rigors, a fact that is quite inexplicable if rigors are caused by reflex irritation of the deep part of the urethra.

Operations upon recent strictures are more liable to be followed by rigors than those upon old and dense cartilaginous ones and the frequency of their occurrence is very greatly influenced by the amount and the roughness of the manipulation to which the stricture is subjected. The rigors that occur after operations for stricture rarely follow immediately. Nearly always they begin shortly after the first act of micturition and the longer this is postponed the less the risk. They may, however, be brought on the following day and even the day after that by any sudden chill. I have several times known a rigor occur for the first time after the fifth or sixth act of micturition because the patient, who had grown careless from immunity, got out of bed to pass urine and stood with bare feet upon some oilcloth. In comparison they are rare after operations upon the bladder. I have never known one occur after suprapubic cystotomy, but they sometimes follow when the incision is made in the perineum.

On the other hand, rigors are quite common after exploration of the kidney in cases of septic pyelitis and occur, irrespectively of sex, in women as frequently as they do in men. They differ from urethral rigors in this, that they may begin immediately after the operation. I have known a patient who was suffering from septic pyelitis for which it was thought advisable to drain the kidney seized with a rigor before she had recovered from the anæsthetic. A second followed a few hours later, but neither had the least effect upon the patient's convalescence which progressed without interruption from the first. These facts all point to absorption as the cause, while it is impossible to account for them on the hypothesis of nerve irritation. The difference in the length of time between the operation and the rigor in the case of the kidneys and the urethra is an instance in point. When there is septic pyelitis the symptoms may begin at once, because the poison that has collected in the pelvis of the kidney is driven by the manipulation directly into the torn and injured blood-vessels. On the other hand, in stricture of the urethra there is no pressure upon the urine and no absorption until micturition takes place. Then the rigor follows within a few minutes. Operations upon the meatus

Digitized by Google

are quite exempt and cystotomy and external urethrotomy are almost so, because the wound is so wide and free that there is no pressure. For the same reason, because the wound is more tortuous, they are more likely to occur after perineal cystotomy than after the suprapubic operation. Old cartilaginous strictures enjoy much greater immunity than recent ones. The cellular tissue is so dense and hard that no absorption can take place.

Free division of a stricture often puts an end to the rigors that occur when a catheter is passed because removal of the obstruction does away to a large extent with the increased pressure when micturition takes place. Tying in a catheter prevents rigors for the same reason; there is no pressure of fluid down the urethra when the bladder empties itself. If micturition is delayed for some hours after a stricture has been divided there is much less risk of a rigor than if urine is passed immediately. The wound is glazed over and absorption does not take place so readily. For the same reason rigors that occur on the second or third day are generally less severe and often need some additional cause such as a sudden chill to start them.

But the strongest argument in favour of the septic origin of these rigors is the fact that they can be prevented by adopting suitable antiseptic measures—measures that would not be of the least use if the cause were the irritation of local nerves. The first essential is to clear out the intestinal canal thoroughly. I do not mean to say that the bacillus that causes rigors always comes directly or indirectly from the intestine, though I am sure that it has done so in some cases. But there can be no question that the intestine is the chief nursing ground for it and that it is eminently desirable to get it as clear as possible. For some days beforehand the patient should be given two or three grains of salol six or eight times in the twenty-four hours. If given in larger amounts the salol may melt and run together during digestion and then later crystallise out again and form an intestinal concretion. If the urine is alkaline from the presence of a fixed alkali benzonaphthol is to be preferred, given in cachets, as it breaks up in the intestine into β naphthol and benzoic acid. Three days before the operation the patient should be given a calomel purge, followed by an effervescing draught and again the night before. The amount of calomel can, of course, have little direct influence upon the growth of septic organisms in the intestines, but as to its value clinically I have not the slightest doubt. The patient should be very warmly clad for the operation, especially if ether is given. There can be no question that cold can precipitate if it cannot cause a shivering fit. Immediately before the operation the glans penis, prepuce, and meatus should be thoroughly washed with soap and water and then with corrosive sublimate solution (1 in 1000). The urethra itself must be cleansed as perfectly as it can be with a boracic acid douche and a catheter that admits of a return current along the walls. It is impossible to get it quite aseptic, but by passing the catheter into the fossa navicularis and washing that out thoroughly, then pushing it in a little further and repeating the process, and finally carrying it down to the face of the stricture the anterior part of the urethra can be fairly well cleared. The portion behind the stricture is of course unapproachable at this period. The instruments should be sterilised and kept from contamination by wrapping them in a carbolised towel. As few as possible should be used and the less manipulation the better, so long of course as the dilatation or division is effectually performed. At the end of the operation the bladder should be emptied by means of a catheter and two drachms of a 2 per cent. solution of nitrate of silver injected into the deep part of the urethra and on to the face of the stricture and left there. The nitrate is decomposed at once into the chloride, which is thrown down as an insoluble powder on the surface of the mucous membrane acting as an effectual germicide.

Micturition should be postponed for as long as possible after the operation in order that the surface of the wound may become glazed over and the patient should not be allowed under any circumstances to get out of bed or expose himself to the least chill. In one case under my care in which, in spite of all my precautions, two rigors did occur after a stricture had been divided further trouble was prevented by injecting some nitrate of silver into the urethra at the seat of the stricture and tying a catheter into the bladder. If rigors were really due to reflex irritation the latter proceeding would undoubtedly have made them worse. As a matter of fact, in conjunction with the nitrate of silver, it stopped them by preventing further absorption. All the other measures that are usually recommended, such as allowing the patient to empty his bladder while sitting in a hot bath and giving hot tea, quinine, opium, and brandy, I have tried thoroughly, and I have come to the conclusion that though they may lessen the patient's discomfort when rigors actually occur they do little or nothing in the way of preventing them.

These are the reasons why I regard urinary rigors as a form of septic poisoning due mainly, if not entirely, to the bacillus coli. The presence of the bacillus can be demonstrated in the vast majority of cases. It is certainly capable of producing toxins of sufficient virulence even when the dose is infinitesimally small. Everything that favours absorption increases the likelihood of rigors. Conversely, everything that checks it tends to prevent them. And the most effectual method of stopping them altogether, one that rarely fails, is the injection of a powerful germicide on to the spot where it may be presumed the organism is most abundant and absorption most likely to occur. It is a mistake to speak of rigors like these by the name of urinary fever—fever due to re-absorption of some of the constituents of the urine. It overlooks the true cause, gives an entirely wrong impression, and, what is much more important, leads to a wrong method of treatment.

Harveian Lectures

ON

SYPHILITIC DISEASES OF THE EYE AND ITS APPENDAGES.

Delivered before the Harveian Society on Dec. 2nd, 9th, and 16th, 1897,

BY HENRY E. JULER, F.R.C.S. ENG.,

OPHTHALMIC SURGEON TO ST. MARY'S HOSPITAL; SURGEON TO THE ROYAL WESTMINSTER OPHTHALMIC HOSPITAL; AND CONSULTING OPHTHALMIC SURGEON TO THE LONDON LOCK HOSPITALS.

LECTURE II.[1]

Delivered on Dec. 9th, 1897.

GENTLEMEN,—This evening I propose to deal with the diseases of the eyeball itself caused by acquired syphilis. My first lecture embraced the subject of the diseases of the appendages. The final lecture will take into consideration those diseases of the eye and its appendages caused by hereditary syphilis.

THE CORNEA.

Inflammation of the cornea is a very common affection of hereditary syphilis, indeed, so frequent is it that its value as a diagnostic sign cannot be over-estimated. To acknowledge that a patient has interstitial keratitis is almost paramount to saying he is the victim of hereditary syphilis. You will admit, therefore, that it is a remarkable fact that it is a disease almost unknown in the acquired form. So far as I am aware only one case has been recorded in England. The sufferer was a patient under the care of the late Mr. Wordsworth and the details of the case are published by Stanford Morton in the Ophthalmic Hospital reports. Stedman Bull[2] classifies no less than four different kinds of inflammation of the cornea due to acquired syphilis. In the *Clinical Journal* this year Jonathan Hutchinson states definitely that he has seen only one case, the one referred to above. A form of keratitis due to acquired syphilis is described by Mauthner[3] as consisting of punctiform infiltrations of the substantia propria. It is the same as the keratitis interstitialis punctiformis specifica of Hock. These dots of opacity must be distinguished from those deposits situated on the back of Descemet's membrane which have received the appellation "keratitis punctata," for this is not a corneal inflammation at all, but a sign of sero-plastic irido-cyclitis. Greeff states that acquired

Digitized by Google

syphilis occurring in infancy is that which is most frequently followed by interstitial inflammation. This is a revelation of great interest and seems to point out that the corneal tissue is more susceptible to the poisonous influences of syphilis in childhood than in adult life. My experience is limited to a single case which was under my care some years ago.

CASE 1.—The patient, a young married woman, consulted me for inflamed eyes. The right eye had been inflamed for a fortnight; so far as she could tell, it had never been inflamed before. A peculiar striated condition of the cornea was seen, giving the cornea a diffuse cloudy appearance. The right vision was $\frac{6}{9}$ Sn. The left eye had been inflamed for two months and the cornea presented punctate and striate opacities similar to, but more pronounced than, the right cornea. Iritis co-existed. The left eye could only dimly see fingers at one metre. There was a gumma of the periosteum at the left angle of the lower jaw. There was no history of syphilis, but she had been pregnant three times, the first two resulting in miscarriages, the third time she gave birth to a living child at the time I saw her eleven months old only, but apparently quite a healthy bairn. Treated with atropine locally and iodide of potassium internally she soon improved so that in April the right vision was $\frac{6}{6}$, the left vision was $\frac{6}{9}$ Sn., and the inflammatory symptoms had disappeared as well as the periosteal node on the inferior maxilla.

I believe this case to have been one of *keratitis punctata profunda* of Mauthner caused by acquired syphilis. It is interesting to note that the opacities showed distinct striations, an appearance especially drawn attention to by Morton in the case he published.

THE SCLERA.

Syphilitic episcleritis and gumma of the sclera are not separate affections. This tertiary manifestation of syphilis is recognised as a circumscribed growth superficial to the sclera in the ciliary zone of the eye. It is quite possible that a syphilitic deposit might occur behind the eyeball, but its recognition would be difficult. In a case to be presently described this actually did occur. Those situated in front are always covered by inflamed conjunctiva, are yellowish-white in colour, and do not appear to be very vascular. A good example of gummatous scleritis came under the care of my colleague, Mr. John Griffith, at the Royal Westminster Hospital about a year ago. A firm yellow node was seen over the ciliary region just below the cornea. The outline of it was easily perceptible through the lower lid. The sufferer acquired the chancre only three months before. Under iodide of potassium it disappeared. Two cases of suspected gumma of the sclera were reported as well as depicted in the Transactions of the Ophthalmological Society for 1891,[4] one by Silcock which disappeared under appropriate treatment, the other by Lawford, but the treatment adopted in his case is not recorded. Gummata of the sclera or episcleral tissue are rare, and I can only boast of having seen the three cases just referred to, though a case of ulceration of the ocular conjunctiva involving the sclera even to perforation has been under my care at St. Mary's Hospital due apparently to syphilis, a lesion rarer and more serious than a gumma. It was not, so far as my notes record, preceded by a syphilitic node.

CASE 2.—The patient, a man of advanced middle age, attended St. Mary's Hospital some five years ago, having a cutaneous ulcer just below the inner canthus of his right eye. It was as large, and even larger, than a sixpence. The pre-auricular or submaxillary glands were not enlarged. He was advised to come into the hospital, but no bed being vacant he went away. The ulcer was considered malignant. He applied some vaseline to the ulcer and when he attended again it was decidedly smaller, 6 mm. × 6 mm. There was considerable conjunctival inflammation below. On Dec. 10th he attended with a perforating ulcer of his cornea and prolapse of the iris without any obvious cause. Also, a deep ulcer of ocular conjunctiva and sclera, at the bottom of which the uveal pigment could be seen. History of syphilis was imperfect. He had suffered from buboes. He was ordered a mercurial lotion for the eye and a mixture of iodide of potassium and bark. He came again on Jan. 10th, 1893—i.e., a month later—and the cutaneous ulcer had almost disappeared, being now about 2 mm. in diameter and the scleral and corneal ulcers were quite healed.

Though my notes do not say that the ulcer at the inner canthus underwent complete cicatrisation I believe it did. The evidence of syphilis is not strong though more suggestive of that disease than any other. Of the three tunics of the eyeball, the middle or vascular coat is more prone to suffer from syphilis than the others. The tunica vasculosa is subdivided from before backwards into iris, ciliary body, and choroid. I will take the parts in that rotation; especially is this advisable as there is a tendency for syphilis to attack each in its turn and in that order.

THE IRIS AND CILIARY BODY.

Syphilitic iritis presents three varieties—plastic iritis, serous iritis, and gummatous iritis. Syphilis is not the only cause of plastic iritis, it may be brought about by gout, rheumatism, gonorrhœa, diabetes, and other causes. I venture, therefore, to throw out the question, Is there any sign which is pathognomonic of syphilitic iritis? and I answer it emphatically, No. There are certain minor points, points of comparison only, in the clinical history which to an acute observer may assist him apart from entering into collateral evidence, but it is the patient's antecedents, the presence of active syphilis, rash, sore throat, mucous patches, &c., which determine the nature of the exciting cause. Let me call to your mind the chief signs of plastic iritis. These are circumcorneal redness, contracted and inactive pupil, and loss of brilliancy of the iris. The colour is changed, a blue appears green, and a brown iris a dirty mud-like colour. The visual acuity is much diminished, pain, and other subjective phenomena are present. We find all these signs in syphilitic iritis. A drop of atropine instilled followed by irregular dilatation of the pupil is absolute proof in doubtful cases. Pain is not, however, unusually severe as it is in gouty, rheumatic, and gonorrhœal iritis. The exudation, on the other hand, and the consequent alteration in colour is more pronounced. These variations by comparison are not very striking, even if you have one of each before you, hence a single case of the one or the other cannot, by the signs presented alone, be a trustworthy guide as to the cause. A previous history of iritis in the same eye is, however, of assistance, for the rheumatic class of iritis has a tendency to relapse—it is its striking feature—whereas syphilitic iritis rarely recurs, and if it does we suspect gross lesions within the eyeball. It nearly always attacks both eyes, either simultaneously or successively. Let me quote a typical example of syphilitic iritis, though I know you must all be very familiar with it:—

CASE 3.—The patient, a domestic servant, came to me at St. Mary's Hospital complaining of redness and slight pain in her left eye. The iris was slightly discoloured, the pupil was contracted and inactive, and there was circumcorneal redness. There were no nodules on the iris. The vision of the right eye equalled $\frac{6}{6}$ Sn. She had a sore throat at the time, the fauces were congested, and mucous patches were visible on the soft palate and tonsils. She gave a history of rash two months previously, but this had faded away. Under the use of atropine drops locally, and constitutional treatment by mercurial inunctions she got quite well.

This is a typical case of syphilitic iritis; it illustrates accurately its chief features—the sub-acute nature of the affection, its occurrence about the fourth or fifth month of the disease from the probable date of contagion, the absence of any pathognomonic sign in the lesion itself, and its perfect amenity to treatment.

Syphilitic iritis appears, as a rule, within the first nine months of contagion and it is safe to conclude that if that period has elapsed the danger of iritis is past. It must be remembered that iritis is not by any means a constant manifestation of secondary syphilis. It occurs in only about 4 per cent. The usual time is during the fourth or fifth month as happened in the case just cited. Hutchinson gives a slightly wider limit; he says: "It usually occurs from three to six months after the chancre." Deposits on the iris and within its stroma of circumscribed nodules of lymph, chiefly near the pupillary margin of the iris, multiple, and orange- or rust-coloured, have received the appellation of gummata of the iris or *iritis gummosa*. This form is absolutely characteristic of syphilis, it occurs in 18 per cent.[5] of all cases of plastic iritis; the absence, however, of these specific changes on the iris does not by any means exclude syphilis as the exciting cause. Gummatous iritis usually appears as a secondary manifestation; it may, however, occur late in this stage. A neglected form of simple plastic iritis is prone to present these so-called "gummata" in its substance. Another clinical fact of importance is the certainty that in this variety a broad synechia will remain. I never remember having seen a typical gummatous iritis clear up without leaving one broad adhesion or more to the capsule of the lens, whilst in rare cases it happens that the nodules from the iris are so large as to abut against the posterior surface of the cornea where they become adherent and appear as black deposits. After the recession of the gumma by treatment the pigmented spot on the cornea remains as an anterior synechia and is connected with the tissue. I well remember a case of this kind which occurred in a young man about twenty-five years of

[4] Transactions of the Ophthalmological Society, vol. xi.

[5] Alexander: Syphilis und Auge, 1887, Wiesbaden.

Digitized by Google

age who was under my care about ten years ago, but I have been unable to find the notes of his case.

There is a variety of iritis accompanied by small multiple growths on its surface which may possibly be mistaken for gummatous. It is called *granuloma of the iris* and is, so far as I know, not syphilitic. The growths are pale, translucent, grey deposits. They clear up entirely without leaving any change visible in the iris and never, so far as my knowledge goes, leave any adhesions to the lens capsule. Two cases of the kind I remember well and have their notes. They both had associated with the iritis keratitis punctata and other evidences of cyclitis. The following is a brief record of one of these instances of granuloma of the iris not caused by syphilis.

CASE 4. — The patient when he came under my care had failure of vision in both eyes. Twelve months before he had noticed his sight dim and under the club medical officer he got quite well. In November, 1889, he had another attack of dimness and consulted his club medical officer again, but did not improve, so came to the Royal Westminster Ophthalmic Hospital. The condition of his eyes was as follows: the pupils were semi-dilated, there were keratitis punctata, slight circumcorneal redness, and vitreous opacities. His vision was reduced to recognising large objects only; he could count fingers held up before him. The vision equalled $\frac{1}{60}$. Mercurial inunctions and atropine were prescribed, although there was no reason to suspect syphilis either hereditary or acquired. Four days later it was noticed that there were small gelatinous-looking growths on the surface of both irides. Mercury and the drops were continued and three months later there was marked improvement. The vision of the right eye equalled $\frac{1}{4}$ and that of the left eye $\frac{1}{12}$. He now had slight mercurial stomatitis, so the drug was discontinued for a fortnight and chlorate of potash gargle was prescribed. The nodules were also much smaller and one had disappeared from the right eye. By June the nodules had all disappeared without leaving any trace behind. He had now ceased taking mercury for five weeks and was taking quinine. In September, 1890, the media were clear, but traces of keratitis punctata still persisted. The vision of the right eye equalled $\frac{6}{9}$ and Jaeger 1 and that of the left eye $\frac{6}{12}$; fingers could be counted at two metres. There were glaucoma, cupping of the disc, with atrophy of the optic nerve. There was no subsequent change when last seen in 1896 beyond the disappearance of the remaining dots on Descemet's membrane.

I have perfect confidence in this patient's statement with regard to syphilis nor could I elicit any history of any constitutional complaint in his family likely to produce this trouble. He had never been abroad and was a healthy, robust-looking fellow.

Another form of iritis which occurs invariably in association with inflammation of the ciliary body is the so-called "serous iritis." A better name would be "sero-plastic irido-cyclitis," for a few iridic adhesions may occur showing that the iris is inflamed and lymph is thrown out, but the evidences of cyclitis are predominant—viz., "keratitis punctata," deep anterior chamber, increased intraocular tension, and a tendency to dilatation of the pupil rather than a congestive miosis. It is an inflammation which usually attacks both eyes as a late secondary or tertiary manifestation and though in my opinion it is a disease which should be classed together with those signs seen in the period of relapses or "reminders" yet it does very often develop as a tertiary phenomenon. This opinion has been urged by Brailey[6] who brought forward cases in evidence of his assertion. As examples of irido-cyclitis as a tertiary manifestation may be quoted the following:—

CASE 5.—The patient, a young married woman, came to me with the story that "both eyes became suddenly inflamed five days ago." Both pupils were dilated owing to the use of atropine before she came to me. Tension in each eye was normal. There were keratitis punctata and circumcorneal injection. The media were hazy and V. = $\frac{6}{9}$ Sn. In the right eye two small posterior synechiæ were present. "She had had five children, no miscarriages. The first child, seven years old, was rickety, had snuffles, and a rash all over the body when fourteen days old. The second child had snuffles. The third child was rickety. The fourth child died as a baby from wasting. She had lost her hair in great quantities before the birth of the first child."

Though no proof of syphilis the history was certainly in favour of it and she must have acquired it before the birth of her first child. If so the irido-cyclitis appeared seven years or more after the initial lesion. There was no other cause that could have accounted for the eye affection.

The inflammatory signs of sero-plastic irido-cyclitis are, as a rule, less pronounced than the true plastic syphilitic iritis and it is a more chronic affection. Although it is slower in yielding to the subtle influences of mercury and iodide of potassium it does subside completely under that treatment. It will yield to mercury alone or to iodide of potassium, but the combination is more effectual. The tension is frequently raised in cyclitis and though it is scarcely ever that operative interference is called for, yet a timely paracentesis of the anterior chamber will have its reward.

It is necessary to consider the question of diagnosis between iritis gummosa and tuberculous iritis. In both we find growths of the iris and in both we usually see plastic iritis; apart from the history and collateral evidence we are quite capable of deciding the one from the other by the appearance of the eye. So evident are the points of distinction that a mistake can scarcely be made. If we re-call to memory the appearance of gummatous iritis—orange-coloured nodules at the pupillary margin, intense redness of the ocular conjunctiva, pain and tenderness of the eyeball, photophobia and lacrymation — we find they disagree almost at every point from those in tubercle of the iris. The tuberculous growths are white, tend to coalesce, are situated chiefly in the iridic angle and grow inwards from the periphery. The dead-white growth often *appears* to be a corneal opacity. Sometimes the tuberculous deposit is marrow-red, but never orange, and with the absence of pain or subjective phenomena beyond gradual loss of sight, combined with persistent growth in spite of treatment, we have little difficulty in determining the nature of the lesion. Again, in tuberculous irido-cyclitis the tension is usually reduced, but in gummatous it is normal.

The recognition of iritis, whether it be the *simple plastic*, the so-called "*gummatous*" (*iritis papulosa* of Alexander), or the *sero-plastic*, in their earliest stage is of the greatest consequence both to the medical man and to the patient. In all we have certain signs present pointing to inflammation of the iris—viz., turbidity of the aqueous humour, loss of lustre in the iris, blurring of the pupillary margin, sluggish action of the pupil, circumcorneal redness, and impaired vision. In one we have growths on the iris absolutely characteristic of syphilitic iritis; in the serous form we have a semi-dilated pupil and "keratitis punctata." This latter sign is recognised by a cloudiness of the lower third or half of the cornea and the discrete dots of which it is composed are readily seen with a magnifying lens. It is not necessary here to dwell upon the distinctions between iritis and other diseases of the eye attended with redness, such as the different forms of ophthalmia, keratitis, acute glaucoma and the like, for in doing so I should be wandering from my subject; moreover, I have already considered the differential diagnosis of some of the more important iridic diseases.

In using the term "*gummatous*" in connexion with iritis attended with deposits on the iris do not misunderstand me. I do not wish you to think they are real gummata. The term is a misnomer, and perhaps the expression *iritis papulosa* given to it by Alexander[7] would be preferable and less misleading. He would restrict this title to those cases of iritis occurring in the secondary stage of syphilis and reserve quite rightly the epithet "*gummatous*" to a tertiary syphiloma of the iris, upholding thereby the generally accepted opinion that a gumma is a manifestation of tertiary syphilis. A true *gumma of the iris* is a much larger growth, is usually single, and starting in the iridic angle grows into the anterior chamber. It may increase to the size of a pea or larger, pushing the lens backwards. It is usually fawn-coloured, is much rarer than the so-called gumma of secondary syphilis, and much more serious. The treatment of syphilitic iritis resolves itself into the exhibition of drugs for the general disease and the use of atropine or some efficient mydriatic locally. There is no special point of distinction to be considered between the local treatment of iritis due to syphilis and that caused by other complaints. It must be borne in mind that in all cases of "iritis gummosa" broad adhesions to the capsule of the lens are often inevitable. Yet in spite of this perfect vision is usually restored to the eye, nor need a second attack be feared, so that on the whole the prognosis is favourable.

It has already been mentioned that inflammation of the ciliary body is a late secondary or tertiary manifestation. There is besides sero-plastic cyclitis another syphilitic lesion which may attack this region—the ciliary body may be the seat of a gumma. This is essentially a tertiary manifestation. Two cases have been recently published, one by Dr. Campbell Highet[8] and the other by Mr. Vernon Cargill.[9]

I have no notes recorded of ciliary gummata nor can I call to my memory any case that I have seen except

as a pathological specimen In the Museum of the Royal Westminster Ophthalmic Hospital there is a jelly preparation of a gumma of the ciliary body and one of the choroid near the optic disc. The patient was under the care of Mr. Adams Frost at the Royal Westminster Ophthalmic Hospital in 1891. She had attended in October, 1890, with fine vitreous opacities which cleared up under pilocarpin injections hypodermically and exposed to view choroiditis consisting of pale roundish areas devoid of pigmentation. In February, 1891, R.V. = $\frac{6}{6}$, L.V. = $\frac{6}{9}$; soon afterwards the vitreous of the left eye became opaque, the eye painful and inflamed. There was bulging of one part of the ciliary region and the eye was excised. The choroid near the posterior pole is thickened to 2·5 mm. and consists of a pale grey opaque mass, which has perforated the sclera and is continuous with a similar but larger mass in Tenon's capsule. There is a similar but smaller growth in the ciliary region.

(To be continued.)

THE VACCINATION PROBLEM: A CONTRIBUTION TO ITS SOLUTION.[1]

BY FRANCIS T. BOND, B.A., M.D. LOND., F.R.S. EDIN.,
HONORARY SECRETARY TO THE JENNER SOCIETY.

[DR. BOND commenced by defining the vaccination problem as one consisting of two parts, the first, "Is vaccination a protection against small-pox and if so to what extent and under what conditions?" Assuming this question to be answered in a sense favourable to the advocates of vaccination there arises the second question, "How far is it expedient and practicable to enforce vaccination on the community generally?" The solution of the first question rests upon scientific facts and statistics and the judges of these facts and statistics are the medical profession throughout the world. Dr. Bond then went on to speak of the late Royal Commission. He mentioned its constitution, how it sat for seven years, and finally the decision it arrived at on the first question. He continued:]

In their report eleven of the thirteen surviving Commissioners have given a decision as to the first half of the vaccination problem that fully confirms the opinion as to the efficiency of vaccination as a protection against small-pox which the leading medical authorities in all parts of the world have for many years held. The conclusions at which they arrived may be summarised as follows: (1) that vaccination diminishes liability to attack by small-pox; (2) that when attack does occur in properly vaccinated individuals their vaccination renders the disease milder and less fatal; (3) that protection against attack is greatest during the years immediately following vaccination, and that the period of highest protection may perhaps be fairly stated as covering nine or ten years; (4) that after the period of highest protective potency the efficacy of vaccination against attack is considerable for the next five years, and possibly never altogether ceases, but that it rapidly diminishes; (5) that the power of vaccination to modify attack outlasts its power to protect against attack, and that its efficacy in this respect is still very considerable, even during the later periods of life; and (6) that re-vaccination restores protection, but that this restored protection again diminishes, and should be renewed, if it be desired to ensure the highest degree of protection which vaccination can give.

As to the safety of vaccination the Commissioners state: "A careful examination of the facts which have been brought under our notice has enabled us to arrive at the conclusion that, although some of the dangers said to attend vaccination are undoubtedly real and not inconsiderable in gross amount, yet when considered in relation to the extent of vaccination work done they are insignificant. There is further reason to believe that they are diminishing under the better precautions of the present day and with the addition of the further precautions which experience suggests will do so still more in the future." With reference to the possibility of replacing vaccination by any other substitute, especially by isolation, the Commissioners state: "We can see nothing then to warrant the conclusion that in this country vaccination might safely be abandoned and replaced by a system of isolation."

The verdict of the Commission is given with a caution of expression that has been represented as an indication of weakness of conviction, but which is clearly the outcome of a studied judicial deliverance on a highly complicated problem. Of the real strength of their convictions as to the efficacy of vaccination the Commissioners have left no room for doubt or misrepresentation,[2] for they have founded on them recommendations for the continuance of the present State machinery for vaccination which would on any other supposition be wholly unjustifiable, even the two Commissioners who have dissented from the majority in some of the most important conclusions at which their colleagues have arrived having joined them in these recommendations. So far, therefore, as it is possible for any problem to be solved by painstaking, competent, and honest inquiry this first section of the vaccination problem must be looked upon as finally settled. Those who refuse to accept the solution of it thus offered, who claim that their views were not adequately represented on the Commission or who insinuate that it was "packed" at its formation with members who had committed themselves beforehand to a verdict, may be honest in their belief on these points, however difficult it may be to look on them in this light, but they will not easily persuade reasonable men to accept such an untenable position.

[As to the second question Dr. Bond said that a doubt as to the desirability of enforcing vaccination might co-exist with a belief in its efficacy because—and this is the view to which the majority of the Commissioners appeared to lean—"the results of compulsion as hitherto practised show that it is not expedient, in the interests of vaccination itself and consequently of the community generally, to attempt to enforce it, at any rate in the way in which this has been hitherto done. It is this aspect of the vaccination problem, with its mingled ethical, political, and administrative considerations, that it is proposed here to discuss."]

PREVIOUS ATTEMPTS TO SOLVE THE PROBLEM.

It is well at the outset to bear in mind that the problem requires us to deal with the demand of a dissentient minority, not only for the entire abrogation of a law which has been in operation for half a century, but for the dissolution of an organisation which has for the same period been maintained by the State for facilitating in the public interest the acquirement of the protection which the law was intended to enforce.[3] Under ordinary circumstances this sort of problem is solved by the simple process of enforcing the law without

[1] Abstract of a paper read before the Sanitary Congress at Leeds on Sept. 15th, 1897.

[2] Further evidence in illustration of this important point is to be found in the statement since made by Lord Herschell of the openness of mind with which he commenced the inquiry and of the conviction forced upon him by the evidence submitted to the Commission. Lord Herschell said (see report of speech at a meeting to promote a National Jenner Memorial): "A vast amount of material was considered by the Royal Commission, and it fell to my lot to have to digest that material and analyse it and submit a report for the consideration of my colleagues. In that task I determined to follow boldly the facts which experience disclosed wherever these might lead. I laid down in the first instance the tests that seemed most fitting to enable an answer to be furnished to the question, 'Is vaccination, or is it not, a preventive of the disease of small-pox and a cause of the modification of the disease where it occurs?' I applied those tests, I can honestly say, entirely ignorant of the conclusions to which they could lead. I was myself surprised at the force of the evidence which was afforded in favour of vaccination. The report which I prepared was submitted to the criticism of my colleagues. Amongst them were some by no means favourable to vaccination, to put the matter not too strongly, and we availed ourselves of the benefit of all their criticism. Wherever they pointed out that undue weight had been given to this fact, that this or that consideration had not been sufficiently weighed, we made modifications to meet these criticisms." After dealing with some of the statistics of vaccination in several English towns Lord Herschell observed: "Is it not difficult for any human reason to get over a collection of facts such as those, and all the more when we find this not only the result ascertained by combining the cases in all those different towns, but that the same phenomenon is observed if you deal with the case of each town separately and if you deal with the separate districts of a town. Such facts as these should be pointedly called to public attention. Yet they are only a small part of the case. It would be impossible to resist the case in favour of the efficacy of vaccination if there were no other facts, but I could mention many other facts drawn not only from our own country but other countries also." See also speech by Professor Michael Foster, Secretary of the Royal Society, in report of meeting, published by the Jenner Society.

[3] The objects of the National Anti-Vaccination League are stated in its prospectus to be "the entire repeal of the Vaccination Acts, the disestablishment and disendowment of the practice of vaccination, and the abolition of all regulations in regard to vaccination as conditions of employment in State departments or of admission to educational or other institutions."

Digitized by Google

respect to the objections, whether honest or otherwise, of dissentients. And in the present case this solution has been steadily tried for nearly fifty years, but with results which cannot be said to be altogether satisfactory. For though an overwhelming majority of the infant portion of the community whom the law was specially intended to protect have for many years under its influence escaped small-pox, the opposition to vaccination which existed even fifty years ago has not diminished but has, on the contrary, decidedly augmented and children in increasing numbers are escaping its protection. What is more striking still is that this has occurred in spite of the steady accumulation of evidence confirmatory of the value of Jenner's great discovery from all parts of the world. But the climax of the paradox is reached when we find that this opposition doggedly maintain its claims notwithstanding the crushing verdict delivered against it by the Royal Commission.

THEIR IMPERFECT SUCCESS.

It is clear, therefore, that so far as the extinction of the agitation against vaccination is concerned the policy of the past cannot be said to have been a success. The chief reason for this steady increase of opposition is to be found in the defects of the procedure by which vaccination itself has been carried out. The evidence submitted to the Royal Commission and embodied in its report shows conclusively that however much this procedure may have commended itself to those by whom it was suggested five and forty years ago practical experience of its working has revealed various weak points in it which of themselves go a long way to account for the opposition that has grown up against it. One of these points in particular so far transcends all the others in importance that it might alone account for much of the antagonism which compulsory infant vaccination had encountered. The employment of human lymph, by transmission from arm to arm, was the only procedure at the date of the passing of the Vaccination Acts that suggested itself as either practicable or effective for the object in view. But it has, through the allegation of dangers which are in an "insignificant"[4] degree real but mainly exaggerated or unfounded, become since that date the chief cause of this increase of the agitation against vaccination. And if we had now no alternative but to continue this method of administering vaccination the difficulty of solving the problem which we have before us would be very serious. Fortunately, however, this is no longer the case, since we have in calf-lymph, prepared as it can now be by methods which guarantee it against any probabilities of taint, a medium for the performance of vaccination which reduces still further even the infinitesimal amount of risk which the report of the Commission recognises as attaching to human lymph. With the general employment of calf-lymph therefore, especially if it be carried to the doors of those who are to be vaccinated, as the Commissioners recommend, and accompanied as they also suggest by such free medical attendance as may in some cases be required, we may confidently expect that a considerable proportion of the opposition to vaccination will disappear.

THE OPPOSITION TO VACCINATION NOT ENTIRELY ERADICABLE.

But we must not suppose that an agitation which has existed for so many years and to which so many persons have publicly committed themselves will collapse all at once even after the removal of this objection, or that an antagonism which is so largely founded on ignorance and sentiment to an operation so free from risk as vaccination will be under the improved procedure which the Commissioners recommend will altogether cease. Objections have been hitherto directed against arm-to arm vaccination; now they are being turned against calf lymph, and there will still be those who will refuse to have their infant children vaccinated on any conditions. This brings us to a second and more perplexing aspect of the vaccination problem.

HOW IS IT TO BE DEALT WITH?

There are some who in their enthusiasm for vaccination and their intolerance of "faddism" will no doubt urge that the mode of promoting vaccination which the law at present prescribes should be left undisturbed. They will argue, and not altogether without reason, that before we in any degree abandon a safeguard against small-pox which the report of the Vaccination Commission has shown to be an effective one, we ought to see what will be the result of the adoption of those administrative improvements which the Commissioners recommend. But a very little consideration should suffice to convince the most uncompromising advocate of compulsion that such a course, however theoretically defensible, is impracticable. The Commissioners have unanimously recommended that some concession should be made to persistent objectors and the unanimous recommendation of such a body as the late Royal Commission cannot be disregarded. Moreover, in some cases we have to deal not merely with the resistance of individuals but of communities like Leicester; and however possible it may be to coerce the former no Government is likely to commit itself to any scheme for the compulsory vaccination of a whole town. Burke asserted that an indictment will not lie against a nation, and the results of the imprisonment of the Keighley Board of Guardians no less than the caution which has subsequently characterised the exercise by the Local Government Board of the powers with which the law has entrusted it in this matter seem to show that it is almost as difficult to enforce a *mandamus* against a recalcitrant vaccination authority.

But though we may recognise the necessity of giving effect to this recommendation of the Commission it is of the first importance that in so doing we should also bear in mind the spirit in which it was evidently made at any rate by the large majority of the Commissioners and that we should at the same time have in view some considerations which they have not in their report fully discussed.

VIEWS OF THE ROYAL COMMISSION ON THIS POINT.

And here it must be remarked that the majority of the Commissioners, whilst distinctly indicating their opinion that it is expedient that some concession should be made to those who are somewhat vaguely designated as "honestly" objecting to the vaccination of their children, make no satisfactory recommendation as to how this is to be done so as to avoid the danger which they distinctly deprecate of opening the door to wholesale evasion. The risk of such a result is obvious, but the only suggestion which they offer towards a solution of this the most puzzling portion of the problem is that if any parent who entertains such an objection is prepared to make a formal statement to that effect no further proceedings shall be taken against him. Now this suggestion obviously involves two distinct assumptions—viz., that a certain amount of pressure, direct and indirect, towards vaccination shall still be maintained as the general law, but that persons who "honestly" object to obeying it shall be formally relieved from so doing. And it is well also to note here two other points. The first is that the exception which the Commissioners thus propose to make for the first time in the history of British legislation is not based, as has been above shown, upon any doubts as to the efficacy of vaccination as a protection against small-pox. Upon this point, as has been above indicated, the report of the Commission leaves no room for question. Even the two Commissioners[5] who declined to sign it and who have stated at great length what they conceive to be a justification for their refusal have nowhere denied that vaccination is in some degree a prophylactic. They only question the degree of protection and the length of time for which the protection is effective. The large majority of the Commissioners distinctly express the hope that their report "will stimulate belief in the efficacy of vaccination that it will remove some misapprehensions and reassure some who take an exaggerated view of the risks connected with the operation as well as lead to a more ready enforcement of the law by local authorities."

THE GROUNDS ON WHICH THE COMMISSIONERS BASE THEIR SUGGESTION.

The Commissioners base their suggestion solely on the grounds of expediency and on the interests of the community generally. They assert that in the case of "indolent or indifferent" parents no right can be admitted on their part to neglect to have their children vaccinated, because "it is better for the child and better for the community that it

[4] See report of Royal Commission, Section 434: "A careful examination of the facts which have been brought under our notice has enabled us to arrive at the conclusion that although some of the dangers said to attend vaccination are undoubtedly real and not inconsiderable in gross amount, yet when considered in relation to the amount of vaccination work done they are insignificant."

[5] Dr. Collins and Mr. Allanson Picton.

Digitized by Google

should be vaccinated than that it should remain unvaccinated. A parent can have no inherent right under the circumstances to which we have alluded to prevent or neglect its vaccination." The second point in connexion with the suggestion of the Commissioners which it is desirable to note is that the exemption from obeying the law which would be thus conceded to the "honest" objector would, for anything that appears to the contrary, be perpetual. There is nothing in the report to suggest that a parent who had once made a declaration would ever be troubled again or that a child who had thus been withdrawn from the operation of the law, even though under circumstances of a temporary character, would not be practically exempt from compulsory vaccination for life unless becoming subsequently a candidate for employment in the service of the State.

HOW WILL IT WORK?

Let us assume then, as we are bound to do, that the recommendation of the Commissioners is a defensible one and that it is not expedient to endeavour to enforce a law which cannot by any attempt to enforce it against determined objectors be made certainly effective. But it will assuredly be asked, What are the cases which are to be thus treated exceptionally and how is it proposed to differentiate them from those in which some attempt at compulsion must be inferred from the suggestions of the Commissioners themselves to be justifiable?

ANOTHER COURSE.

It would seem that if a parent is desirous of obtaining exemption from vaccination for his child he should be required to appear in person before the justices as at present and to apply for an order to that effect.

[As summarised by Dr. Bond his suggestions were as follows: That the object of the Commissioners can be attained with the least risk to the community, with the least disturbance of the present law, and with reasonable consideration to those who are affected by it by the magistrates exercising more largely than they have hitherto done the discretion with regard to the enforcement of vaccination which the law already gives them; by an extension of that discretion so far as may be necessary and of the principle of temporary suspension of vaccination which is already recognised by the law in cases where it may appear expedient; and also by providing for the distinction between *defaulters* through negligence or indifference and *objectors* who urge sufficient grounds for their objection by giving the latter an opportunity of applying voluntarily to a court of summary jurisdiction for an order for the suspension of the vaccination of their children instead of their being required to be summoned as at present. That it is expedient, in justice to objectors no less than in the interest of the community generally, that in any case in which objection to the vaccination of a child is made on the ground that injury from vaccination has been experienced in the family of the objector or that there is special reason for fearing danger therefrom to the child, competent inquiry should be made into such allegations and a report thereon presented to the justices for their information as well as for that of the public.]

The suggestions of the Commissioners if adopted without safeguards would practically involve the withdrawal of the child from the control which the State should exercise over him in vaccination as well as in other matters in his own interests as well as in those of the public health. They are open also to another objection, for they involve the creation of a dangerous precedent which if once established might be drawn into use in other matters, since it might be reasonably urged that if the children of those who object to vaccination are to be exempted altogether and in perpetuity from the operation of the vaccination law, why should not those whose parents object to education, factory, and other protective legislation be equally exempted? The key to this part of the vaccination problem is to be found in the provision which the law already recognises for temporarily suspending vaccination where there is sufficient reason for so doing, though probably some statutory extension of this discretion may be required in order to indicate clearly to the magistracy the course which it is desirable for them to pursue. Such a course, apart from the advantage which it offers of avoiding a dangerous precedent, includes as will be presently shown others which greatly commend it for adoption.

ADVANTAGES OF THIS PLAN.

It cannot be denied that to properly carry out the plan thus suggested will involve a good deal more trouble both to the magistrates and their clerks than they have hitherto been in the habit of taking with vaccination cases. They will have to recognise that their duties in regard to them are not simply ministerial but judicial. It will also involve a large amount of new work for the medical officer of health. But these are considerations to meet which involves no insuperable difficulty. The work will, no doubt, be heavy at first, but it will gradually lessen as the mode of dealing with it becomes more familiar both to the public and the judiciary and as precedents are established they will simplify routine. On the other hand the gain will be enormous. In the first place the objector to infant vaccination, whether honest or otherwise, will no longer be able to trade on the cry that he is denied the simplest rudiments of justice, the opportunity of showing cause why he should not be punished. He may object to the decision of the magistrate but there will be always the reply that this case has been considered and that the grounds on which his objection has been dealt with are in evidence. This is of itself a great advantage so far as the cause of vaccination is concerned for it will remove a strong and reasonable source of public sympathy which at present exists and it is also only common justice to the objector himself. But there is another advantage which is of no less moment in the interest of vaccination and of the public generally. Nothing is more certain than that the cause of vaccination has suffered greatly not only from the injudicious enthusiasm of its friends but from the want of any organised effort to meet and expose the fallacies and misrepresentations of its opponents. There are various ways in which this latter object can be accomplished, but there is no better way than by competent inquiry into statements of mischief which vaccination is alleged to have produced and by exposing as publicly as possible misconceptions as to facts upon which opposition to it is so largely founded. A police-court may not be the *beau ideal* machinery which would be selected for the purpose of doing this work if any better were available; but it has the recommendation of being ready to hand, of being already recognised by the law as adapted for the purpose, and it is capable of being made still further suitable by the aid of the improved procedure suggested. If used in this way it is believed that it will become a valuable means of education not only to the public generally but to the magistrates themselves, who will be necessarily led to take a less perfunctory view of their duties in this matter than they have hitherto done. In Scotland, where vaccination prosecutions are conducted before the sheriff, a highly-trained legal official, these proceedings are much more creditably managed than they are as a rule in England.

It may be safely asserted that if such machinery for the formal investigation of allegations against vaccination had been in existence ten years ago a great deal of unfounded objection against it would have been brushed away. And it may be added that if there were any doubt about the cause of vaccination emerging with credit from such inquiries it would not be worth defending at all. But they may be safely left to those whose experience as medical officers of health enables them better than anyone else to appreciate the value of vaccination as a defence against small-pox and who have no possible interest in exaggerating it. It cannot be too strongly insisted on that vaccination has been discredited in the past by misconception, on the one side, mainly due to misrepresentation playing upon ignorance; and on the other by undue confidence shutting its eyes to patent facts and making no effort to meet the organised attack upon it which has for more than ten years been persistently carried on. No small share in this result also has been due to the careless way in which vaccination prosecutions have too often been conducted and to the unreadiness of the magistrates to embark on inquiries for which they have probably felt themselves to be unfitted in the absence of skilled assistance. The prosecuting authority, the board of guardians, even when they have exhibited any interest in the matter, have generally been represented by the vaccination officer, who though capable of conducting the proceedings if unopposed is as a rule quite unfitted to meet the adroit defence which has been for some years brought to bear upon them. It is a considerable recommendation of the proposal to transfer the administration of the Vaccination Acts from Poor-law to sanitary authorities that it would bring the whole procedure into the hands of officials who may be expected to take an intelligent interest in it because it is so important a branch of public health work. But whatever may be done in this direction it is imperative, if the errors of the past are to be retrieved and the public are to be effectually protected against recurring epidemics of small-pox, to

Digitized by Google

treat objections to vaccination on the part of parents with consideration when they are entitled to it; to remedy the defects of vaccination procedure which experience has demonstrated; and, above all, to lose no opportunity of educating the public to judge intelligently for themselves on which side the truth lies.

(To be continued.)

A CASE OF INCOMPLETE RUPTURE OF THE RIGHT VENTRICLE, WITH ADHERENT PERICARDIUM.

BY DAVID HUNTER, M.A., M.B., B.C. CANTAB.,
PATHOLOGIST TO THE COUNTY ASYLUM, WHITTINGHAM, LANCASHIRE.

A MARRIED woman, aged seventy-seven years (at death), was admitted to the County Asylum, Whittingham, in July, 1876, suffering from chronic mania and secondary dementia. The notes soon after her admission state that she was in only moderate health, but no organic disease was found. Her weight on admission was 10 st. 10 lb. and she had since become exceedingly obese. There is no record of any serious illness during her stay in the asylum until September, 1892, when she was confined to bed for a few weeks with pyrexia, swelling of one knee and leg, and dyspnœa. The cardiac action had been feeble for the last ten years and she had been liable to cyanosis and swelling of the feet and ankles, but no cardiac bruit could be detected at any time. Mentally she had become more and more demented and childish and she had been subject to periodical attacks of excitement, being of late as a rule cheerful and garrulous with many senile delusions of identity. On Nov. 19th, 1897, after three or four sleepless and restless nights, she was noticed to have some dyspnœa and to be unusually cyanosed. The temperature was subnormal, the respirations were 23 per minute and laboured, and the pulse was 80, being very feeble. She was kept in bed and was treated with appropriate stimulants; she improved slightly until the 21st, when she rather suddenly became worse. The symptoms were collapse with very low temperature (94° F.), respirations from 30 to 44, shallow and laboured, much cyanosis of the face and extremities, cold sweats, vomiting with much retching, and retention of urine. The pulse was 80 per minute and almost imperceptible. She retained consciousness the whole time, and complained of difficulty in breathing and tightness across the chest, but owing to her mental condition it was uncertain whether there was any severe pain. During this time and for the next two or three days she slept fairly well at night and took nourishment freely. Her general condition remained much the same until the 24th when the dyspnœa became worse and she died at 10.50 P.M.

Necropsy.—A post-mortem examination was made on Nov. 25th at 2 P.M., when the body was found to be enormously obese. The brain showed thickening of the membranes, general cerebral atrophy, a morbid degree of sub-pial felting, and dilatation of the lateral ventricles, with granularity of the ependyma; there was also slight atheroma of the basal vessels. The pericardium was thickened and showed complete firm adhesion between its layers with no sign of recent inflammation. The heart was enlarged and globular. There was a considerable excess of epicardial fat and the walls of both ventricles were thickened. The right ventricle was much dilated and the left to a less extent. The right side of the heart was engorged with soft dark clot. In addition to the fatty overgrowth and infiltration in the walls the myocardium showed advanced fatty degeneration, especially that of the right ventricle, the muscular fibres being pale, soft, and friable—indeed scarcely distinguishable from the epicardial fat. On the anterior surface of the right ventricle immediately under the dense superficial stratum of the epicardium there was seen a small extravasation of soft, dark clot—about 2 cm. in diameter—slightly bulging the membrane outwards, and on section this was seen to communicate with the right ventricular cavity by an irregular narrow channel with ragged, softened, and reddened walls, a small clot connecting the extravasation on the surface with the mass of clot in the ventricle. The valves were healthy save for slight chronic thickening of the mitral cusps and dilatation of the tricuspid orifice. The first part of the aorta showed some atheromatous degeneration. The weight of the heart was 450 grammes. Each lung weighed 420 grammes. There was emphysema of the free borders. The tissue was indurated, brown, and tough, with considerable œdema. Each pleural cavity contained about 340 c.c. of clear fluid. There were no pleuritic adhesions. The liver weighed 1120 grammes and was pale and friable. There were four irregular dark-brown calculi in the gall-bladder with a few cubic centimetres of almost colourless mucus. The spleen weighed 100 grammes and was pale, soft, and friable. The kidneys showed advanced chronic interstitial nephritis; a large amount of peri-renal fat was present. The stomach was dilated. The intestines were small and shrivelled in appearance. There were large deposits of fat in the omentum.

Remarks.—Rupture of the right ventricle is a comparatively rare occurrence, about three-fourths of the cases of cardiac rupture recorded having taken place in the left ventricle. In this case the rupture was evidently prevented from becoming complete by the firm pericardial adhesions. The conditions necessary to bring about changes in the myocardium favourable to the occurrence of rupture were many—fatty overgrowth, with great general obesity, senility, adherent pericardium, and chronic interstitial nephritis. One of the most prominent symptoms in such cases—namely, severe cardiac pain—appeared to be absent, but as stated above, owing to the patient's condition of dementia, this is not certain. For the clinical notes of this case I am indebted to my colleague, Dr. W. R. Dix.

Whittingham.

A CASE OF TETANUS COMPLICATING ULCERS OF THE LEG TREATED WITH ANTITOXIN; RECOVERY.[1]

BY E. J. SMYTH, M.D., B.S. LOND.,
ASSISTANT MEDICAL OFFICER TO THE WANDSWORTH AND CLAPHAM UNION INFIRMARY, S.W.

THE patient was a woman, aged sixty years, who was admitted to the Wandsworth Infirmary on the evening of Aug. 19th, 1897. Her previous history was unimportant; she had had one attack of rheumatic fever and had suffered from ulceration of the right leg for about two years. Her present illness, as stated by a friend, dated from four days previously and commenced with stiffness of the lower jaw which had now become quite fixed, the patient being scarcely able to speak or swallow. She complained also of great pain in the jaws, at the back of the neck, and in her chest and back, more or less constant but subject to paroxysms of aggravation at varying intervals. On admission there were general rigidity of the whole body, retraction of the head and slight tendency to opisthotonos; marked trismus, the masseters being firmly contracted and the jaws closed; while the majority of the trunk muscles were also firmly contracted. The condition of the latter varied a good deal, especially that of the abdominal muscles which were at times much more tense than at others. There were slight spasms of the muscles of the head and trunk at varying intervals of from two or three to ten minutes accompanied by risus sardonicus, increased retraction of the head, and opisthotonos, but at no time were these so severe as to cause any distress in breathing though accompanied by a good deal of pain and cyanosis. The patient was emaciated and in a weakly state generally; sordes were present on the lips and she complained of great thirst. The tongue could not be seen and she could only swallow with great difficulty and in small quantities at a time. The heart's action was slightly irregular, the pulse 96, and the temperature subnormal. Two chronic ulcers were present in the lower part of the right leg on each lateral surface respectively; they were unhealthy in appearance the bases being covered with sloughs and foul discharge and the skin around inflamed. No other wound or breach of surface was present.

She was ordered rectal feeding and a supply of anti-tetanic serum was at once sent for, 10 c.c. (prepared by the British

[1] The patient was shown at a meeting of the South-West London Medical Society, Oct. 13th, 1897.

Digitized by Google

nstitute of Preventive Medicine) being injected five hours later under the skin of the abdomen. On the following morning (Aug. 20th) she was in much the same condition, though the muscles of the lower jaw were rather more relaxed and the patient could swallow slightly better. The spasms were still occurring frequently but the intervals increased in length later in the day. At 3 30 P M. 10 c c. of serum were again injected, and at 8.30 she seemed decidedly better and was sleeping quietly. On Aug 21st her condition was not markedly changed and, as the ulcers remained very foul in spite of frequent dressing, the patient was anæsthetised with chloroform, the surfaces were scraped, and strong carbolic lotion was vigorously applied. She also had another injection of serum in the morning and during the rest of the day the spasms were less frequent, this being no doubt in part due to the effects of the chloroform. The temperature rose slightly in the evening for the first time. On the 22nd she appeared to be worse, the spasms being more frequent and more severe than at any previous time and the temperature at 6 A M. being 101·2° F.: 10 c c. of serum were again injected and about half an hour later the spasms became decidedly less frequent, the patient appearing to be generally better in the evening. She was also ordered twenty grains each of bromide of potassium and chloral three times a day per rectum. She was still being fed by nutrient enemata and stimulants were given freely. On the 23rd she expressed herself as feeling better though complaining of pain in the ulcers which were still very unhealthy looking; the spasms were rather more frequent but the opisthotonos was less marked; 10 c c. of serum were injected at 11 A M and at 12.30 P.M. there was no sign of spasms and the patient was sleeping quietly. The temperature in the evening was 98°. On the 24th her condition was unchanged, the spasms having recurred and being at times fairly frequent. Another injection was given in the morning. The ulcers now for the first time were noticed to be somewhat cleaner and the sloughs seemed separating. On the 25th there was no material change; an injection was given in the afternoon and the chloral and bromide mixture was omitted. On the 26th there was no improvement and in the evening the temperature rose slightly, the breathing became more rapid, and the spasms were occurring as before; 10 c.c. of serum were again injected in the evening. During the next two days no change of importance occurred. Another injection was given on the 27th about midnight. On the 29th she was worse, the ulcers also having become more offensive; the pulse was feeble and the temperature slightly raised. On the 30th no improvement in her general condition was noticed, though she appeared to swallow slightly better and could take some nourishment by the mouth; another injection of serum was given on this date. On the 31st there was decided diminution of the spasms and she could swallow well without their occurrence. The ulcers, however, showed no improvement and her general condition during the next two days was weaker if anything. On Sept. 2nd she had another injection, which was the last given. The spasms had now disappeared, and from this time she began to show signs of improvement. Two days later the ulcers also appeared to be healthier and their surfaces cleaner. On the 6th she was decidedly better and the muscles generally were more relaxed.

The further history of the case was uneventful and the patient improved steadily after this time. On Sept. 11th there was general relaxation of the trunk and neck muscles, though slight rigidity of the limbs on passive movement was noticed for two or three weeks afterwards. On the 15th she could open her mouth well and protrude her tongue, and the ulcers showed signs of healing. On Sept. 23rd she could sit up with assistance, but was still very weak. She continued to improve physically and the ulcers were healing steadily, but four or five weeks later she began to develop symptoms of melancholia associated with delusions of persecution, which unfortunately persisted and have since necessitated her removal to an asylum.

Remarks.—Although numerous successful cases have now been recorded in connexion with the antitoxin treatment of tetanus and its efficacy I suppose, especially in those of the chronic variety and with long incubation period, conclusively established there are several points in the present case which I think are worthy of note; and first I would call attention to the nature of the wounds, one or both of which presumably gave access to the tetanus bacillus—viz., two chronic ulcers of the leg. The rarity with which such a common condition is complicated with tetanus is, I think, of interest, and I have not been able to find a record of any similar case either among those recently published or in any text-book, the disease being, as is well known, most commonly associated with punctured, contused, or lacerated wounds, especially of the hands or feet. As to the exact means of infection and the period of incubation no definite facts could be obtained in this particular case.

With regard to the effects of the serum and its bearing on the ultimate result of the case of course nothing definite can be said, especially as other means were employed. It should be noted, however, that several of the injections, especially in the early part of the treatment, were followed by marked amelioration and diminution in the frequency of the spasms, and the influence of the antitoxin in this direction has been observed in many of the cases so treated which have been reported in the columns of THE LANCET, even amongst those with a fatal termination. The effect of the serum on the general condition was very doubtful, and though slight rise of temperature followed the earlier injections no constant result occurred. A temporary improvement certainly appeared to follow the first few but after this for about a week the patient seemed to become slightly and progressively worse, so that during this period little hope was entertained of her recovery. The fact that the ulcers showed no sign of improvement until the general symptoms abated is also a point of some interest, I think. The total number of injections given was eleven and beyond slight reddening of the skin and transient tenderness on one or two occasions no local disturbances were produced, the injections being given under the skin of the abdomen on every occasion. Part of the serum used was that prepared by the British Institute of Preventive Medicine, while the rest was prepared at the Pasteur Institute in Paris.

I am permitted to publish these notes through the kindness of Dr. J. Brevard Neal, Medical Superintendent of the Infirmary.

New Wandsworth, S.W.

DIAPHRAGMATIC HERNIA; PERFORATION OF THE STOMACH.

BY T. E. H. FISHER, M.R.C.S. ENG., L.R.C.P. LOND.

AT 6.30 P.M. on Oct. 18th I was called to see a man, aged fifty years. His history was as follows. He had suffered off and on from pain after food and distension for years. The pain was sometimes so severe that he rolled about the floor until vomiting relieved him. For the last two months these attacks had been more pronounced in character. On Oct. 17th he felt quite well until after taking a cup of tea about 5 P.M., when slight gastric pain, flatulence, and distension came on. The pain grew worse and kept him awake the greater part of the night. It was spasmodic and localised to the epigastrium. Next morning, feeling no better, he tried to make himself vomit, but only succeeded with difficulty in bringing up some mucus with a good deal of flatus. In the afternoon he vomited three or four times and was doing so when I arrived. He complained of nausea with pain and distension in the abdomen. The vomit shown me was an odourless brown fluid. On examination there was slight distension with resistance and tenderness in the epigastrium. On percussion a tympanitic note extended out to the anterior axillary line as high as the sixth rib, being bounded above by the normal cardiac dulness and apparently due to a dilated stomach. The lower abdomen moved well. The liver dulness was normal. With respect to the lungs nothing abnormal was detected save a few crepitations over the right. The heart was normal. The patient was ordered a bismuth mixture with fomentations and to have a soap-and-water enema with turpentine in the morning. When I saw him again (at 12 A.M. on Oct. 19th) he had had no more vomiting but the pain was worse. He was twisting about in bed bringing up flatus at intervals. The enema had brought away a soft formed motion with flatus. I ordered twenty grains of sulphate of zinc hourly for three doses. The emetic not acting at 4 30 P.M. I attempted to wash out the stomach with the ordinary rubber syphon. Half a pint of water was with difficulty introduced and immediately and forcibly thrown back, flatus accompanying it. On examination the epigastric

Digitized by Google

distention, resistance, and tenderness had increased. The left side gave a tympanitic note as before, changing to a dull one in the angle between the ribs, and on the right side extending below the ribs for two inches. On deep palpation a swelling could be felt in the epigastrium like an india-rubber bag. The pulse was by this time distinctly weaker, the pain was evidently severe, the patient looked anxious, and was very restless. Considering the obscurity of his symptoms I advised a second opinion with a view to sending him to a hospital for exploratory operation. Mr. Morgan, of West Green, saw him with me one and a half hours afterwards. He quite concurred in the advisability of getting him away, but doubted if he would stand the journey. The patient's condition by now was very bad, the extremities were getting cold, and the pulse was almost imperceptible. The abdominal signs were unaltered. While a cab was being ordered to take him to St. Bartholomew's Hospital I left the house for a short time. In that interval he walked down stairs. After a hypodermic injection of morphia he was carried out to the cab. The journey was well borne till towards the end when he collapsed a good deal. Dr. Briggs, the senior house surgeon, saw him at the hospital. The patient was promptly taken in. The abdominal dulness had disappeared and was replaced by a high note suggesting a huge dilated stomach. He died at 10 40 P.M.

Necropsy.—I am indebted to the courtesy of Mr. James Berry, surgical registrar, for the following full notes of the post-mortem examination performed on Oct. 22nd. The external appearance was rather thin. There was much post-mortem decomposition. The abdomen was much distended. There was emphysema about the scrotum, head, and neck. The skull, brain, tongue, larynx, and thyroid were all normal. The chest, heart, and pericardium were normal and not obviously displaced. The pleuræ were normal except as below. There was a good deal of recent congestion in the right lung. The left lung was much shrunken, and occupying only the upper part of the left pleura. There were no adhesions and no disease. Bulging into the left side of the chest and covered by normal pleura was a large, nearly globular sac measuring between 4 in. and 5 in. in diameter. It had a broad pedicle at the inner and lower part and was clearly a diaphragmatic hernia. The peritoneal cavity contained free gas. The lesser peritoneal cavity was greatly distended and filled with a thin, nearly black fluid looking like altered blood. This sac formed a huge globular mass occupying most of the left upper quadrant of the abdomen. The transverse colon ran across the lower front part. The intestines, large and small, were quite healthy everywhere. The stomach was remarkably abnormal both in shape and position. About one-half of it, the cardiac end, was greatly distended, forming a rounded sac some 6 in. in diameter. This portion bulged into the lesser peritoneal sac above mentioned. At the lower border was a small perforation through which blackish fluid was oozing into the peritoneal cavity mixed with small particles of food. A fairly well-marked and evidently old constriction separated this half of the stomach from the pyloric half which was in the hernial sac above mentioned. Nothing else but stomach was in this sac and there was no inflammation, congestion, or other sign of strangulation. When drawn out of the sac the whole stomach was seen to be enormously dilated, and the lesser omentum was greatly widened, being seven inches across at its widest part. A constriction at the pylorus marked the lower limit of the part that had been in the sac. The cardiac portion of the stomach was considerably decomposed and it was difficult to say whether the perforation was ante- or post-mortem. It seemed probable, however, that it occurred a few hours before death on account of the large quantity of fluid distending the lesser peritoneal sac. The opening in the diaphragm through which the hernia occurred was oval (or nearly round) and measured about two inches in diameter. It was situated just to the left of the œsophageal opening, the herniated portion of the stomach passing in front of the œsophagus and before entering the hernial sac. The hernial opening appeared to have been congenital and the stomach had evidently been in the habit of passing freely into the hernial sac for a long time; it was very easily reduced by pulling and had probably often been spontaneously reduced. There was no sign of any old injury to the ribs, liver, diaphragm, or any other part. The gall-bladder was much shrunken and contained nothing but two calculi each as large as a cherry-stone. They were tightly grasped by the walls of the gall-bladder. Around the gall-bladder were a few old adhesions, evidently the result of old inflammation. There was no disease of any other abdominal viscus.

Remarks.—This case appears to present unusual features in a good many respects. The symptoms were obscure, but towards the latter part of the second day pointed to some grave mischief in the upper abdomen. At first it presented all the appearances of a dilated stomach with subacute gastritis. There was no dyspnœa or sign suggesting pneumothorax. The alteration in the physical signs by the time the patient arrived at the hospital suggest that the gastric perforation was ante-mortem. If it occurred post mortem it is a little difficult to understand what determined the sudden fatal collapse. From his history he had had many attacks beginning as this one did. I have to thank Mr. James Berry and Dr. J. A. O. Briggs for their kindness in giving me all the information at their command.

Wightman-road, N.

PULMONARY ABSCESS; OPERATION; RECOVERY.

BY ARNOLD EDWARDS, M.D., CH.B. VICT.,

HONORARY SURGEON TO THE CHORLTON-UPON MEDLOCK DISPENSARY, MANCHESTER.

A WOMAN, aged twenty-one years, was first seen by my friend, Mr. H. Dumville Harthan of Salford, on Jan. 8th, 1897, when she complained of acute pain in the right half of the chest, troublesome cough, and a very abundant fœtid expectoration. Previously to this she appeared to have been ill for some five or six weeks with symptoms of pleuro-pneumonia on the right side. The patient's father died from phthisis and there was also a tuberculous family history on the maternal side. On Jan. 23rd I was asked by Mr. Harthan to see the case with him. The patient was then very thin, flushed, and short of breath, with a weak, husky, whispering voice, breathing at the rate of 33 per minute, with a paroxysmal distressing cough resulting in the daily expectoration of a pint or more of highly offensive thin watery pus and mucus. The tongue was dry and thickly-coated with a brownish fur. Pain, slight but occasionally stabbing in character, was complained of at the back of the right side of the chest. The temperature was 102° F. and the pulse was 128. The apex beat could be felt in its normal position. The whole chest moved badly, the right side hardly moving at all. On percussion there was dulness over the lower half of the right side of the chest posteriorly and laterally. On auscultation numerous moist sounds were to be heard over both lungs, but these sounds were much coarser, in fact gurgling in character and accompanied with bronchial breathing, just below the angle of the right scapula. Vocal fremitus and vocal resonance were slightly diminished throughout the dull area. Guided by the greatest intensity of the physical signs, I introduced a sterilised exploring needle into the eighth intercostal space immediately below the angle of the right scapula. Nothing resulted until the point of the instrument had travelled from two and a half to three inches directly forwards, then the barrel of the syringe filled with pus of rather thin consistency and free from flocculi slightly stained with blood, and of a most penetrating foul odour. Examination of this fluid and also of the sputum for tubercle bacilli proved entirely negative. In spite of the patient's low condition, operation was decided upon as offering the best chance of recovery.

An operation was performed on Jan. 24th. The patient was placed in an almost completely prone position, chloroform was administered by Mr. Harthan and my brother, Dr. Fox Edwards, assisted me. Introduction of the exploring needle under antiseptic precautions into the sixth intercostal space along the mid-axillary line resulted in the immediate withdrawal of pure serum entirely free from the slightest turbidity or odour. The instrument was now passed for a second time to a depth of about three inches in the situation of the first puncture, and again drew off stinking pus. An incision about two and a half inches long was then made down to the periosteum along the ninth rib immediately below the angle of the right scapula. The

Digitized by Google

periosteum was divided along the course of the rib and reflected with a raspatory and a good inch of rib was removed with bone forceps. A fine trocar and cannula was employed as a guide to the pus, and the track was opened up by sinus forceps and a large cavity was reached in the lung from which about ten or more ounces of fœtid pus and gas escaped. The aperture made by the forceps was further enlarged by passing the finger through about an inch or so of condensed tissue which bled rather profusely at first but the hæmorrhage soon ceased. The abscess cavity appeared to be irregular and was lined with much broken-down and softened material, but its complete exploration was impossible the finger not being long enough to map out its limits with any precision. A wide rubber drainage-tube about six inches long was introduced, no attempt being made to irrigate the abscess cavity. The wound was dressed with a pad of wood-wool freely covered with iodoform. Morphia (¼ grain) combined with atropine ($\frac{1}{150}$th grain) was given hypodermically. By the next day the patient had rallied wonderfully well, the temperature had come down to 99° and the pulse had dropped to 96. The sputum showed marked decrease and was almost odourless. The dressing was saturated with horribly offensive pus, the edges of the wound were covered with a very adherent dirty-grey material and there was some cellulitis in the immediate neighbourhood. On Jan. 27th the temperature again rose to 101° and the pulse reached 114. There was considerable cyanosis with marked laboured breathing and much rambling and the whole body was bathed in perspiration. Fine crepitations and bronchial breathing were to be heard over the greater part of the right lung but there was no appreciable increase in the dulness. A mixture of ammonium carbonate, digitalis, nux vomica, and senega was freely given together with considerable quantities of brandy. The patient's condition for the next few days was very critical but a marked improvement took place on Feb. 3rd. An evening temperature of only 99·2° was then registered, the circulation had improved, the bronchial breathing had disappeared, and the fine crepitations had given way to moist râles. By this time also she had begun to sleep well, the rambling had ceased, and the sweating had markedly diminished. In addition the wound had cleaned, the discharge had become odourless and the sputum quite sweet, and the quantity daily expectorated did not amount to more than an ounce. Three days later the temperature being normal the tube was shortened half an inch. On Feb. 13th she was allowed to sit up for a short time. The tongue had quite cleaned and the appetite was good, there was practically no expectoration and as the discharge through the wound was now slight the tube was shortened to three inches. The after history was uneventful. On Feb. 24th the tube having slipped out it was not replaced and on March 7th, six weeks after the operation, the wound closed. She rapidly gained in weight and strength and is now (December) in perfect health. There is not the slightest sign of cough or trace of expectoration. No retraction or bulging of one side of the chest can be made out, the measurement from the spinous process to mid-sternum at the level of the scar being 15 in. on either side; in fact there is now nothing to show except a cicatrix with some deficiency of resonance and weak breath sounds in its neighbourhood.

Remarks.—This case presents several points of interest. There is, firstly, its successful issue, a sufficient rarity of itself to be worth recording. Another feature was the discovery of a simple serous pleuritic effusion in the vicinity of the pulmonary abscess. Had the aspirating needle hit upon this at the first puncture the correct diagnosis would probably not have been then arrived at and the patient would consequently have lost her life. Again, the rapid obliteration of the large abscess cavity and the few physical signs now remaining to indicate the previous serious condition are also noteworthy.

Manchester.

CORPORATION HOMES AT DARTMOUTH.—At the meeting of the Dartmouth Town Council held on Dec. 10th it was stated that Mr. Richard Burford Searle, L.R.C.P. Lond., M.R.C.S. Eng., had offered £2000 at 3 per cent. interest to the council for carrying out their scheme of corporation homes provided a particular site named by him is available and chosen. He also proposes that on his and his wife's death the property should revert entirely to the corporation.

CASES OF ACUTE ATAXY OF ONE LIMB

BY H. CAMPBELL THOMSON, M.D., M.R.C.P. LOND.,
MEDICAL REGISTRAR TO THE MIDDLESEX HOSPITAL.

THE two cases I have recorded below are interesting examples of an acute onset of ataxy in one limb. They appear to be widely different in origin, for while the first was accompanied by definite symptoms of organic disease the second was apparently functional in character and seemed in some way to be connected with over use of the muscles. Ataxy of acute onset limited to one arm or leg is a rare condition, and when resulting from organic disease of the cord is probably in most cases due to a focal lesion situated somewhere in the posterior columns so that the muscular sense impressions are interrupted. Sir William Gowers[1] mentions a group of cases (to which he has given the name of acute myelitic ataxy) which were characterised by an acute onset of ataxy in one arm accompanied by complete muscular anæsthesia so that all power of estimating weights was lost although the cutaneous sensibility might be perfect. The condition usually reached its height in a few hours, remained complete for some weeks, and then slowly disappeared, and it probably depended upon some organic lesion of an inflammatory character. In the first case given below, although the ataxy was limited to the left arm the other symptoms were widely distributed over the cord and the right arm was the only limb which was not affected in some way or other.

CASE 1.—The patient was a man, aged forty-eight years, who was admitted to the Middlesex Hospital on June 4th, 1896, under the care of Dr. Sidney Coupland, to whose kindness I am indebted for permission to publish the notes. There was nothing of importance in the family history and previously to this illness the patient had never been laid up. He was a man of moderate habits and there was no history of specific disease. On May 29th in the middle of the morning as the patient was walking home he felt giddy and noticed that his left leg seemed heavy, and he also found that he was unable to pass his urine. On reaching home he sat down and did not try to walk again for the rest of the day. Towards the evening he felt some numbness in his left hand, and control over the movements of that limb was lost so much that if he tried to touch his face with his hand, the movements were so erratic that he hurt himself. On the next day (May 30th) there was some weakness of the right leg; it could be moved but the patient was not able to stand. There was no weakness of the right arm. He was admitted into hospital on June 4th complaining of loss of power in the legs and the left arm. On examination it was found that there was some slight weakness of the left arm accompanied by marked incoördination, so that the patient was quite unable to perform simple movements with any degree of accuracy, and he stated that this symptom had been much worse, and was now less marked than it had been. The power of distinguishing weights was not lost and there was no anæsthesia. There was considerable loss of power in the left leg. The limb was extended and turned on its inner side and although some movements could be performed at the knee- and ankle-joints the leg as a whole could not be raised. The right leg was also weak but much less so than the left and it could be raised off the bed. There also seemed to be some loss of movement of the lower intercostal muscles. There was alteration of sensation over the trunk and lower limbs commencing at a line about one inch below the nipple. If the point of a pin was drawn down the chest the pain ceased to be felt at the level of that line and became changed into a dull sensation of touch. Heat and cold could not be recognised with any certainty below the same level. Sensation to touch was considerably diminished and the loss was more marked in the left than in the right leg. There was no anæsthesia of the left arm. There was neither girdle pain nor zone of hyperæsthesia. All control over the sphincters was completely lost and the urine had to be drawn off. The abdominal, plantar, and epigastric reflexes were all absent and so also were the knee-jerks and the deep reflexes of the left arm. There were no bedsores.

[1] Diseases of the Nervous System, vol. i., p. 322.

Digitized by Google

On the 5th the symptoms had improved. The line of anæsthesia was a little lower and the movements of the left arm were more coördinated but still very clumsy. On the 8th the plantar reflex could be obtained on the right side but there was no alteration of the other reflexes. There was also some increase of power in the lower extremities. On the 9th both plantar reflexes could be obtained and there was also a very slight return of knee-jerk on both sides. On the 16th power over the sphincters had returned. The patient from this time continued to improve very rapidly and when seen some weeks afterwards he was quite well, his gait was normal, he had perfect control over the sphincters, and the knee-jerks were both present.

The symptoms in this case make it quite clear that the ataxy depended on an organic lesion, and its mode of onset points to the nature of the lesion being an inflammatory one and of a disseminated type. It is especially interesting to note that there was no anæsthesia of the arm or loss of sensibility to weights but with regard to the latter symptom it must be stated that it was not tested until after the ataxy had begun to improve so that possibly there may have been some sensory alteration when the disease was at its worst. Another important feature of the case was the very rapid recovery which took place, especially with regard to the ataxic symptoms which passed off in a very few days.

CASE 2.—The second case was that of a woman, aged fifty-eight years, who complained of inability to use the left arm. She stated that she was in her usual health until the evening of Sept. 4th when she noticed a tingling in the left arm and hand and she also thought that her left leg dragged a little. She took very little notice of these symptoms until the next day when she found she had lost control over the movements of the left arm. This annoyed her especially at meals, for she was quite unable to guide a fork to her mouth with the left hand and she was afraid to try much lest she should hurt herself. She also found that she dropped things if she held them in the left hand. I saw her first on the 6th, two days after the onset of the symptoms, and there was then still very marked incoördination of the left arm. On attempting to touch any point the fingers went very wide of the mark, so much so that on trying to put her finger to her mouth she missed her face altogether. There was no anæsthesia either over the arm or elsewhere, weights could be well distinguished, and she could also tell what position the limb was put into. There appeared to be some slight weakness of the limb. No definite symptoms could be found in the left leg either motor or sensory. I did not see her again until a week had passed, and by that time the incoördination had almost entirely passed away. She still complained of sensations of numbness, tingling, and coldness all down the left side of the body but no anæsthesia or other objective symptoms could be found. At the end of another week the patient was again seen and the ataxy had then quite disappeared. The coldness of the left side had improved but some tingling and numbness, especially of the left arm, still remained. Otherwise she expressed herself as perfectly well.

With regard to the cause in Case 2 the patient put it down to the fact that she had lately been obliged to carry heavy weights. For three weeks before the attack she had carried a large bucketful of water from the top to the bottom of a house and *vice versâ* and the journey was made altogether about four times a day. She stated that she always used the left hand and that she felt a great strain on coming down stairs as she always kept the arm stiff and held the pail well away from the body in order not to spill the water. There were no signs whatever of any organic lesion in this case. On the whole it seemed probable that fatigue was the cause of a temporary functional derangement of the movements of the limb which caused a loss of harmony between the actions of the different muscles and so produced the clumsy movements.

Queen Anne-street, W.

WEST OF ENGLAND EYE INFIRMARY, EXETER.—The committee of the West of England Eye Infirmary, Exeter, which receives patients from all parts of Devon and Somerset, is anxious to erect a new building on the present site. To carry out their full plans £30,000 would be required, but in order to meet present exigencies £10,000 is asked for. As has been already stated in THE LANCET an anonymous donor has recently given £2000 and on Dec. 10th two anonymous gifts of £1000 and £105 respectively were received.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF OTITIS MEDIA ACUTA HÆMORRHAGICA.

BY J. T. C. NASH, M.B., C.M. EDIN.

A WOMAN, aged forty-seven years, whose powers had been overtaxed by long and incessant nursing and anxiety, was suddenly seized about 2 o'clock one morning with severe pain in both ears. She stated that the pain was very acute for about an hour when the ears went "pop" and blood began to stream from them. When I saw the patient, about 8 A.M., I was shown several pellets of blood-saturated wool while from both ears there still issued a copious sero-sanguineous discharge. Hearing was markedly deficient on both sides. Each drumhead showed a recent tear. There was a history of some ear trouble when a child but of none in the meanwhile. Under careful treatment the discharge ceased after passing through serous and purulent stages. There was at no time any odour. In the course of the affection the mastoid cells on both sides became involved but the inflammation quickly resolved. The patient made a thorough recovery with normal hearing power. The tympana were left only slightly opaque but the tears had healed.

No doubt the early and free hæmorrhage was of benefit. Both ears were simultaneously affected, but the pharynx was not inflamed.

Beckenham.

A NOTE ON A RARE DEFORMITY.

BY CYRIL H. FLORY, M.R.C.S. ENG., L.R.C.P. LOND.

ON Oct. 3rd last a primipara in the course of a natural labour was delivered of a male infant who is bilaterally "club-handed"—that is to say, the child's hands are situated at the lower end of the ulna but articulate loosely with the inner lateral aspect of the same. Both radii are wanting (this is mentioned in text-books as being a usual concomitant condition) and on neither hand is there a thumb. The ulnæ are unusually stout as if to compensate for the first-mentioned deficiency. At birth and for some days afterwards the thenar border of the hand lay alongside the inner border of its ulna, the fingers pointing towards the elbow; this position is now modified, the hands being at right angles with the forearm. Using a little force the hand can be brought to the extremity of the ulna and in the same straight line, but the original position is assumed immediately on releasing. The child is for the rest beautifully shaped and there is nothing in the parental history which would lead one to anticipate such a misfortune.

Overton, Ellesmere.

NOTES ON TWO TYPICAL EXAMPLES OF VARIETIES OF OVARIAN TUMOUR.

BY JAMES OLIVER, M.D., F.R.S. EDIN.,
PHYSICIAN TO THE HOSPITAL FOR WOMEN, SOHO-SQUARE.

CASE 1. *Cholesteatoma; operation; recovery.*—A single woman, aged twenty-five years, began to menstruate at the age of sixteen years. Since its appearance the menstrual discharge had reappeared regularly; it had always been scanty and accompanied by pain, seldom severe, in the lower abdomen. Two years ago the patient had detected a small lump in the hypogastric region. For twenty-one months it seemed to have maintained the same size and as it produced practically no discomfort she paid little heed to its existence. Three months ago she was seized suddenly with severe pain in the lower abdomen and as the pain had continued more or less since its onset and the lump had steadily increased in size I

Digitized by Google

was asked to see her. This attack was not connected with menstruation. On examination I found that the hypogastrium was occupied by a small, central and globular swelling which pushed forward markedly the abdominal wall in its immediate locality. The tumour extended three inches to the left and three inches to the right of the linea alba and its summit was felt at a spot four and a half inches above the pubes. It was very tender to the touch and with difficulty fluctuation could be elicited. Per vaginam the cervix uteri was found to be located rather far back. In front and to the right of the cervix the vaginal roof was pushed down by a somewhat globular swelling, which was fixed and was continuous with the abdominal tumour.

At the operation the tumour was found to be extensively adherent to the anterior abdominal wall and to the floor of the pelvis. After separating the adhesions I transfixed and tied the pedicle and removed the tumour intact. It was a cholesteatoma of the right ovary. The inner lining of the cyst glistened like mother-of-pearl and the fluid teemed with cholesterine and fat.

Remarks.—The cholesteatoma is according to my experience most probably a congenital tumour. It may display no activity until the occurrence of menstruation or the observance of marriage.

CASE 2. *Chondrocystoma; operation; recovery.*—The patient was a woman, aged forty-two years. She had been married twelve years, had had two children and no miscarriage; the last child was born nine years previously. During the last nine months the menstrual discharge which hitherto had recurred regularly had been delayed seven or fourteen days, and had been accompanied with severe pain in the lower abdomen. For six years the patient had complained off and on of pain in the lower abdomen and back. On abdominal examination nothing of note was found, but on vaginal examination the cervix uteri was found to be located well forwards and towards the right wall of the pelvis and the fundus was felt posteriorly in Douglas's pouch; the uterus as a whole was retroverted. To the left of the uterus and in close apposition with it was felt a small moveable swelling of about the size of a hen's egg. This swelling was extremely nodular and very hard.

The patient was operated upon, and the tumour when removed proved to be the left ovary slightly enlarged. Its surface was much corrugated. When cut into it was found to be composed of two loculi, one of which contained clear fluid whilst the other was occupied by two softish bodies of the size of beans floating in a little clear fluid. These bodies were unattached. The wall of the cyst was cartilaginous and was nearly a quarter of an inch thick. The free bodies contained in the tumour appeared to be macerated ovarian stroma.

Remarks.—"Gyroma" is the name given to this variety of tumour by some authorities, but in my opinion it is not so appropriate as "chondrocystoma." It is a benign growth and is in no way related to the endothelioma. The cartilage of which it is composed is fibrous. The loose bodies found in the interior of this tumour appear to be pieces of ovarian stroma macerated and slightly altered.

Gordon-square, W.C.

WITHINGTON FEVER HOSPITAL SCHEME.—A meeting of ratepayers and property owners in Burnage was held on the 4th inst. "to protest against the proposed erection in Burnage of a hospital for infectious diseases by the Withington Urban District Council." The hospital has to be built somewhere and no one objects to it if it is not near them, but only near their friends somewhere else. The common pleas were raised that it would lower the value of property and was unpleasant in a residential district, but the chairman acknowledged that the objections to it "were largely sentimental." He thought the neighbourhood of the Withington workhouse would be a suitable site as there was an isolated area where there were already a workhouse, a crematorium, a destructor, and a cemetery. But this site would no doubt be objected to by the people of Whalley Range, Chorlton-cum-Hardy and West Didsbury, all residential suburbs. Many speeches were made, all more or less in the same strain, though one of the speakers pointed out "that at present there was not a building within a quarter of a mile of the proposed site." It seems [illegible] this protest will be successful, for an "infe[illegible]ital" as it is often called is never welcome [illegible] where there is least resistance.

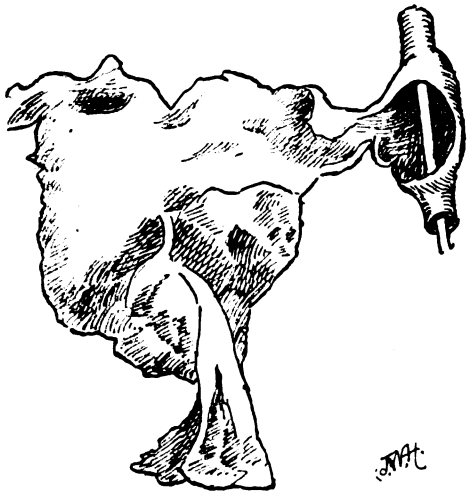
LEEDS GENERAL INFIRMARY.

A CASE OF ANEURYSM OF THE LEFT POPLITEAL ARTERY TREATED BY REMOVAL OF THE ANEURYSMAL PORTION OF THE VESSEL.

(Under the care of Mr. H. LITTLEWOOD.)

EXTIRPATION of the sac of an aneurysm, when possible, is probably the most satisfactory method of treatment of this serious disease of an artery and the results are superior to those following any other method of treatment. P. Delbet[1] collected statistics on the subject and showed that extirpation gave a mortality of 11·32 per cent., while the death-rate from ligature was 18·95 per cent., though it must be remembered that in most of the cases in which extirpation has been applied the aneurysm has been traumatic. It might have been thought that gangrene would have been a more frequent result of this method than of ligature, but it is decidedly less common after extirpation, and the probable explanation is that in ligature the artery is occluded at two points—namely, at the aneurysm and at the point at which the vessel is tied, while in extirpation the continuity of the artery is destroyed only at one spot—namely, where the aneurysm is situated. Of course the method of extirpation has its limits, but at present it is hardly possible to define them as it has not been applied in a very large number of idiopathic aneurysms. For the notes of this case we are indebted to Mr. F. E. Taylor, house surgeon.

A married man, aged twenty-five years, was admitted to the Leeds General Infirmary under the care of Mr. Littlewood on June 9th, 1897, on account of pain and a pulsating tumour in the left popliteal space. He stated that he was engaged as a tailor's presser and stood all day at a table and used with his right hand an iron weighing 24 lb; whilst doing so he had the left leg constantly extended and in advance of the right. He was engaged to do "piece-work" and when in regular employment worked about twelve hours a day. For two months previous to the onset he had been working for fourteen or fifteen hours a day through overtime. The symptoms commenced six weeks before admission. On returning home from his day's work he began at that time to have shooting pains at the back of the left knee and down the leg. The pain was at first slight and appeared in the evenings only. Little notice was then taken of the pain as it was thought to be due to rheumatism and the leg was daily rubbed with some embrocation. The pain gradually increased in severity so that at the end of a week he consulted Dr. Gordon Sharp to whom Mr. Littlewood is indebted for the notes of the case until the time of the patient's admission to the infirmary. When first seen by Dr. Sharp the patient complained of pain in the left popliteal space. He was treated as a case of rheumatism as nothing could be found on examining this region. He was seen a week later when a faint but distinct pulsation could be made out. He was advised to stay in bed, but this he refused to do—in fact he kept to his work (not working overtime) until June 3rd, but he then consented to stay in bed. A few days before this a pulsating swelling could be made out and over this was heard a harsh continuous murmur. From the 3rd until the time of his admission to the infirmary on the 9th he remained in bed. During this time he suffered greatly from pain and the swelling increased in size.



On examining the left lower extremity a pulsating tumour was visible at the back of the knee distending the popliteal space. The circumference of the limb round the middle of the patella measured 16 in., the similar measurement of the other limb being 14 in. The pulsation in the tumour was

[1] Traitement des Anévrysmes externes en général et en particulier. 1839.

Digitized by Google

very distinct both to touch and sight. It was expansile in character. A loud bruit could be heard over it. Pressure on the femoral artery obliterated both the pulsation and the bruit. The swelling was fixed and the skin, which was of normal appearance, was freely moveable over it. The left leg was distinctly warmer than the right. The knee was kept semi-flexed. There was no evidence of arterial disease elsewhere and the heart appeared to be normal. There was no history of syphilis. After admission it became necessary to administer morphia every night on account of pain.

An operation was performed on June 15th. The patient was placed in the prone position and ether was administered. An Esmarch's tourniquet having been placed on the upper part of the thigh an incision about eight inches long was made over the whole length of the popliteal space beginning at its upper limit on the inner side and continued downwards along the middle of the ham. The superficial and deep fasciæ were divided and the internal popliteal nerve was drawn outwards by means of a retractor. The muscles forming the boundaries of the space were then separated and were held aside by means of large retractors so as to expose fully the aneurysmal sac. An attempt to completely dissect out the sac failed owing to the thinness of its walls and in one part it appeared to have become diffuse. The sac was accordingly laid freely open and its contents were turned out. The artery above the sac was then cleared for a short distance, ligatured with moderately fine silk, and divided near the sac. The aneurysmal part was then dissected out from above downwards and a portion of the vessel below the aneurysm was exposed, ligatured, and divided. The aneurysmal portion of the vessel and the greater part of the sac were now removed. All clots and any remaining shreds of the sac were then cleared out of the space and the parts were washed out with some hot solution of biniodide of mercury and made thoroughly dry. The wound was closed with silk-worm gut sutures without any drainage and was dressed with iodoform and cyanide gauze. The whole limb was enveloped in a thick layer of cotton wool and placed between hot bottles. Recovery was uninterrupted. After the operation the pain in the leg entirely disappeared and the patient slept well without morphia being administered. On the third day pulsation could be felt in the posterior tibial artery. On the tenth day the wound was dressed and was found to have healed throughout; the alternate stitches were removed and two days later the remainder. On the fourteenth day the patient

The figure represents the portion of vessel and as much of the sac as was removed in one piece with it.

got up and he left the hospital on July 3rd, eighteen days after the operation. He was shown at the meeting of the Leeds and West Riding Medico-Chirurgical Society on Nov. 5th and was then quite well having returned to his work for some weeks.

The portion of the vessel removed measured about two inches in length. The coats of the vessel where divided looked healthy. The aneurysm appeared to be fusiform, becoming sacculated in its posterior half. The opening into the sac measured about an inch in the vertical and half an inch in the transverse direction. In size the aneurysm was about as large as a goose's egg. The sac was partly filled with dark soft clot; the walls were very thin and in one part appeared to have given way.

Remarks by Mr. LITTLEWOOD.—I am recording this case of popliteal aneurysm as additional evidence in favour of treating aneurysm in accessible regions by the old operation somewhat modified—i.e., the removal of the diseased part—in addition to laying open the sac and tying the vessel above and below. In THE LANCET of Nov. 17th, 1894, there is a paper of mine on this subject with a record of two cases, one of the superficial femoral and the other of the popliteal. Reference is made in this paper to a case of traumatic aneurysm of the ulnar artery treated in February, 1891, by completely dissecting out the sac. Since then I have removed three others: (1) aneurysm of the radial artery at the back of the wrist[2]; (2) diffuse popliteal aneurysm[3]; and (3) the present case. I feel convinced that in the majority of cases this method of treatment is the most satisfactory to adopt. In the case recorded above I soon discovered that it was impossible to remove the sac intact, so without any delay I opened it and turned out the clot. This at once enabled me to find the artery at the upper part of the sac and facilitated its separation, ligation and division. Having done this it was not at all difficult to separate the sac from the surrounding structures and to remove it after ligaturing and dividing the vessel below. In my former cases I feel I have wasted time in attempting to remove the sac intact. Except in the two cases of traumatic aneurysm I have never succeeded. I consider that the attempt causes delay and increases the difficulty of the operation. I now think it better to follow Guattani and lay open the sac before attempting to ligature the vessel. It has been urged by some surgeons that it would be better to follow his method more closely and be content after ligaturing the vessel above and below not to remove the aneurysmal portion. It appears to me that the removal does not make the operation more difficult and there are obvious advantages in getting rid of it. In THE LANCET review of the work of the year 1894 my cases are referred to and this method of excision of the sac is attributed to Antyllus[4]; apparently this is not correct. Antyllus ligatured the vessel above and below the sac; then opened it and turned out the clots but did not excise it. (Apparently none of the original documents of Antyllus can be found.) My friend and colleague Mr. Moynihan, has very kindly furnished me with the following extract bearing on this point from the writings of Oribasius, whose chief work was discovered in the Vatican in 1825. Oribasius (fourth century) quotes Antyllus as saying: "We operate upon aneurysms of the extremities and the head in the following manner. If the aneurysm be by dilatation make a straight incision through the skin in the direction of the length of the vessel and, drawing open the lips of the wound, divide with precautions the membranes which cover the artery. With blunt hooks we isolate the vein from the artery and lay bare on all sides the dilated part of the vessel. After having introduced beneath the artery a probe we raise the tumour and pass along the probe a needle armed with a double thread. Cut the threads near the needle so that there be two threads. Seizing then the ends of the one thread we gently draw it towards one of the two extremities of the aneurysm and tie it carefully. In like manner we also bring the other thread towards the other end of the aneurysm and tie this in its place. Thus the whole aneurysm is between two ligatures. We open then the middle of the tumour by a small incision and in this manner all which it contains will be evacuated and there will be no danger of hæmorrhage. To extirpate the dilated part between the ligatures is a dangerous operation."

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Adjourned Discussion on the Prevention of Enteric Fever.

A MEETING of this society was held on Dec. 14th, the President, Dr. HOWSHIP DICKINSON, being in the chair.

Dr. J. F. PAYNE in continuing the discussion said that the methods of combating the disease had been considerably modified of late years by the discovery of the typhoid bacillus, though its value as a factor was still uncertain since it had not yet been shown that it could communicate the disease to animals. He thought that it was not beyond the bounds of possibility that the organism might at one time exist as a saprophyte and only become pathogenic under given conditions, though this has not been proved and as a rule the disease originates from some previous case. He insisted on the importance of disinfection in the immediate environment of the patient and the disinfection not only of the fæces but also of the urine and the expectoration; he thought that undoubtedly the best method of disinfecting the fæces was to burn them, but the difficulties of carrying out such a method in private houses were considerable and he suggested that the mixing of the fæces with perchloride of mercury and hydrochloric acid was effectual. He then discussed the disinfection of cotton, linen, and woollen garments, &c.; the two former, he said, were easily disinfected, while the last was, he thought, hardly ever disinfected by the ordinary process of washing. He thought it probable that typhoid fever could be acquired in certain cases by inhalation.

Surgeon-Major-General JAMESON showed tables demonstrating the relative frequency and mortality of the disease in various countries. In Bermuda the disease is endemic and although in some stations by hygienic measures the disease seems to have decreased yet in others it seems to have advanced, but it is not in the places where the soil is waterlogged that it has increased but in the places where the dry-earth system is in use. This is well shown in his table, for it is in these places that the highest ratio occurs. He considered that flies were a definite agent in the distribution of enteric fever and they could not be disregarded by the advocates of the dry-earth system, and in this connexion it was most important to attend to the proper sanitation of the kitchen as it was a most difficult thing to keep food from becoming infected in this way. In practice he thought there was difficulty in using the Pasteur filter and he preferred the method of boiling, cooling, and aerating the water. He referred to the micro-organisms which were antagonistic to the typhoid bacillus and mentioned the experiment at Agra of inoculating the water with the Ghadi Ali bacillus during an epidemic of typhoid fever; the epidemic was stopped, but it should also be noted that the water used was at the same time boiled. The disease in India occurs (1) in young soldiers and recent arrivals; women and children suffer less than men; (2) in the frequent occurrence of isolated cases distributed over a wide area; and (3) at posts which in all probability are for the first time occupied.

Professor KANTHACK said that there were two points which he proposed to deal with—(1) source of supply, and (2) distribution of the bacilli in space. In regard to the first point it is commonly supposed that the bacilli exist in the urine and fæces only at the time of the disease. It has, however, been shown that the bacillus exists in the pus of abscesses formed during an attack and may even be found in abscesses some years after the attack. The typhoid bacillus has been shown to occur in the gall-bladder and may occur in this situation years after the attack as shown by Welch. How long the bacillus may remain in the fæces is still uncertain, but it has been shown in the case of cholera that the bacillus exists long after the motions have become solid and therefore it is not probably safe to regard a patient as free from infection as soon as he has recovered from the disease. With regard to the second point Lösener has found the typhoid bacilli in the superficial layers of ploughed lands and this has been confirmed by Pfeiffer and Kolle; they have also been found in conditions when typhoid fever could be excluded. There is then distinct evidence that the typhoid bacillus may thrive and multiply in the soil and from there may enter the water-supply. He thought that considerably more care should be exercised in the post-mortem room in the disinfection of the intestines, &c., removed from a case of typhoid fever.

Dr. SIMS WOODHEAD referred in the first place to the contamination of the water-supply. He thought that undoubtedly the cistern in private houses was an advantage to the community at large but a disadvantage to the family in particular, for although the cistern might be a source of infection to the family yet it afforded protection against the infection of the mains as it was impossible to keep the pressure in them constant. The outbreak of plague at Poona had shown that two methods were of service in checking an epidemic—viz., notification and inspection; and he referred to the recent Clifton epidemic as showing how an epidemic could be stopped by these methods. It was a comparatively easy matter to check an epidemic due to milk infection but a much more difficult matter to deal with one due to the infection of water. He thought that the constant and regular examination of the water-supply was most important as it gave an indication of a change of condition occurring in the supply. The serum test should be applied in all cases and it was of especial importance to obtain evidence in early cases of diarrhœa which are said to precede the outbreak of an endemic of typhoid fever. Metchnikoff has shown that the cholera bacillus may be present in the motions before an attack of cholera and it is not therefore improbable that the typhoid bacillus may be present in the intestines some time before the disease asserts itself. With regard to the organisms that are able to inhibit the growth of the typhoid bacillus there is still uncertainty, but as the typhoid bacillus grows under very similar conditions to the bacillus coli it is probable that where the bacillus coli flourishes there the typhoid bacillus will also flourish.

Mr. W. J. TIVY (Bristol) considered that both influenza and enteric fever had been endemic in Clifton during October and November. The cases of influenza had been of aberrant type and were accompanied with abdominal symptoms. In most of these cases the invasion was sudden and the temperature high, ranging from 102° to 104° F.; diarrhœa was present in many; there was, however, no splenic enlargement or eruption and the cases convalesced in from eight to sixteen days. None of his cases were submitted to Widal's test as according to his opinion the test is deceptive in cases unaccompanied by the usual clinical symptoms of enteric fever, and this view is supported by THE LANCET.[1] Dr. Davies, however, in his remarks before the society on Nov. 23rd, strongly advocated Widal's test as absolutely diagnostic in all doubtful cases and mentioned that in over seventy cases the diagnosis of enteric fever was made certain by it. During the time these cases of influenza were about a sudden and most serious type of enteric fever broke out and in these cases, too, the invasion was sudden; the temperature from the onset was high, from 103° to 105°; delirium was marked; there were severe pains in the limbs; diarrhœa was present in all cases; the rose rash was uncertain. Severe hæmorrhage occurred in many cases and there was splenic enlargement; in fact, after the first week there was no doubt they were enteric, therefore Widal's test was unnecessary. According to Dr. Davies both of these epidemics were enteric fever and as he showed at the last meeting could be traced to the milk-supply of a small farm having fifteen cows and giving 100 quarts of milk in the morning and 40 in the evening; this amount of milk is said to supply 65 large houses containing about 700 people entirely with milk and 81 houses partially; out of the total, according to Dr. Davies's own showing, 66 houses were not attacked through taking the alleged infected milk. Dr. Davies states that the outbreak was due entirely to rinsing the cans and tins, five in number, in impure sewage tainted water; no allegation is made that water was added to the milk. On the other side, the farmer, his wife and daughter who solely manage the dairy and have done so for years positively state that they always with their own hands rinse their cans and tins in boiling pump water only and that they never touch them with cold or unboiled water. The public analyst has not, it is understood, found typhoid bacilli in either the alleged infected water or infected milk and no case of enteric fever has been traced to the neighbourhood of the farm. It is said that on Nov. 20th, seven weeks after the first of these cases occurred, a labourer on the farm was found to be ailing though he had worked every day as usual and by

[1] THE LANCET, Dec. 4th, 1897, p. 1468.

Digitized by Google

Widal's test alone, his blood was decided to be enteric. Mr. Tivy's own views are that there have been two epidemics in Clifton, one of influenza, in which many of the cases had abdominal symptoms. The second and most serious epidemic was one of severe enteric fever produced by sewage air poisoning owing to the utter want of ventilation of the main drains in Clifton and that owing to the prolonged drought in August, September, and October the drains were not properly flushed, and being ill-ventilated sewage air in volumes was forced back chiefly into the houses attacked, which stand on high ground and in close proximity to the large main sewer, which, after descending a steep declivity of about 270 feet, empties itself at all tides directly into the River Avon a short distance below the suspension bridge. The sanitary authorities flushed the drain at the end of October and through November and heavy rain fell and then the epidemic subsided. He believed that unless the main drains were ventilated and the sewage of Bristol and Clifton diverted entirely out of the Avon the present epidemic will be nothing to what will follow should there again be a prolonged drought.

Mr. ADAMS (Maidstone) referred to the diarrhœa which preceded the outbreak of the epidemic of typhoid fever at Maidstone and showed a chart demonstrating that there is no intermission between the preceding diarrhœa and actual outbreak or the epidemic of typhoid fever. The incidence of the usual autumnal diarrhœa is higher in men than in women, while in this attack of diarrhœa the number of women attacked is greater than the number of men attacked and the speaker attributed this to the fact that more women drink water. It is noteworthy that in the cottages near the supposed origin of the infection diarrhœa had been prevalent before the occurrence of a definite case of typhoid fever.

The discussion was again adjourned.

MEDICAL SOCIETY OF LONDON.

Cases of Cysts of the Pancreas treated by Incision and Drainage.

A MEETING of this society was held on Dec. 13th, the President, Dr. SANSOM, being in the chair. The President announced that he had received a letter from Dr. Robert Barnes enclosing £100 as a donation to the society to be applied in whatever way the council might think best.

Mr. ALBAN DORAN read a paper on a case of Pancreatic Cyst treated by Incision and Drainage, with Comments. The patient, a single woman, aged twenty-four years, was admitted into the Samaritan Hospital in May, 1897, on account of a prominent abdominal tumour which had been growing for over two years, in the course of which period she had two attacks of mental depression and spasmodic epigastric pains. The patient concealed these facts which were not obtained till after the operation. There was no positive evidence of injury. The urine was free from sugar. The tumour was prominent, fluctuating, and mobile, lying chiefly in the epigastric and left hypochondriac regions. An exploratory operation was performed as the diagnosis was uncertain and tapping was objectionable. The tumour proved to be a cyst occupying the lesser peritoneal cavity; the lesser omentum and stomach formed the front of its capsule and the transverse meso-colon was entirely below it. It was attached by a broad base to the body of the pancreas near the head and was sutured to the abdominal wound and drained. The cavity contained 44 oz. of a greasy yellow fluid; after draining a clear secretion with amylolytic qualities escaped till the middle of October when the fistula closed. The secretion never irritated the skin though the integuments were naturally sensitive in this patient. Mr. Doran dwelt on the chief features of this case in relation to over a hundred already published. These cysts may occur at any age. One in an infant six months old was recorded by Railton and another in a patient seventy-six years old by Stieda. Much stress was laid on the surgical importance of defining peritoneal relations and the exact attachment of the cyst during the operation. The cyst may lie in the lesser peritoneal cavity or between the folds of the transverse meso-colon or in the general peritoneal cavity. When it occupies the lesser peritoneal cavity, as in Mr. Doran's case, it has probably burst through the peritoneum in front of the pancreas. This would account for the complete freedom of the ascending layer of the transverse meso-colon which is found entirely below the cyst in many of these cases. When a pedicle could be formed, even if it included the tail of the pancreas itself, total removal of the cyst was justifiable. Removal of a sessile cyst on the other hand involved risk of damage to the splenic and other large vessels and to small arteries and veins in the friable pancreatic tissue. The statistics of drainage in the treatment of sessile cysts seemed very satisfactory. Owing to the situation of the cyst in Mr. Doran's case it could not have been drained through the loin. Aspiration and tapping for diagnostic purposes are both perilous and seeking for a calculus during the operation is not without danger.

Dr. ROLLESTON and Mr. G. R TURNER contributed the notes of a case of Peri-Pancreatic Cyst. The patient, a man, aged thirty years, came under observation with a history of epigastric pain of six months' and jaundice of three months' duration; the fæces had been clay-coloured for five months. The skin was deeply jaundiced and itching was a prominent symptom. In the abdomen there was a tense tumour separated from the liver by a band of resonance. From its association with jaundice the tumour was thought to be probably a dilated gall-gladder. Laparotomy, performed by Mr. Turner, showed, however, that it was a cyst arising from the neighbourhood of the pancreas. It contained 30 oz. of dark-brown fluid which owed its colour to methæmoglobin and was not due to bile; a considerable amount of blood-clot separated on standing. Dr. Arthur Latham, who undertook this analysis, found no evidence of the presence of pancreatic ferments. The cyst was tapped and drained and the patient made a good recovery. The cyst was certainly peri-pancreatic, but in the absence of any positive evidence of its being pancreatic it was impossible to say that it was not a hæmorrhage cyst such as might result from injury or pancreatitis. There was, however, no history of traumatism. The association with jaundice was remarkable and since it passed away after tapping and draining it was presumably due to pressure exerted on the bile-ducts by the tense cyst. The fact that the fæces were noticed to be clay-coloured two months before the onset of jaundice might be explained by supposing that the flow of pancreatic juice into the duodenum had been interfered with. Dr. T. J. Walker, of Peterborough, had described a similiar condition of the fæces without jaundice due to obstruction of the pancreatic duct.

Mr. MALCOLM read the notes of a case of Multilocular Cyst of the Tail of the Pancreas which simulated hydronephrosis of the left kidney. Laparotomy was performed and the tumour removed. There was much difficulty in arresting hæmorrhage, but this was eventually done so completely that the wound was closed without drainage. Convalescence was uneventful. The tumour was shown and its contents were described as strongly amylolytic. Mr. Malcolm said that according to Mr. Doran only some dozen cases of complete removal of these cysts were on record, a case recorded by Mr. Clutton and the present one being the only ones operated on and published in this country. A case published by Dr. Malcolm Mackintosh[1] was quoted as showing one mode of death with very obscure and misleading symptoms which might occur when a pancreatic cyst was not treated surgically. The possibility that a tumour might be a pancreatic cyst was urged as as pecial reason for making an exploratory incision.

Mr. G. R. TURNER said that in addition to the case brought forward on that occasion he had recorded another. In both the cyst wall was very thin and difficult to distinguish from peritoneum. Enucleation of the cyst would have been impossible and he agreed with Mr. Doran that it was improper to attempt it in cases such as his. When the cyst was on the left side possibly enucleation in the way Mr. Malcolm had adopted might be advisable. He had drained both of his cases from the front without difficulty. In the first case some hard material was felt at the bottom of the cyst the nature of which was not clear; there was no evidence of malignant disease and the patient was now well four years after the operation. He thought that both of the cysts were in the lesser peritoneal cavity projecting between the stomach and the transverse colon.—The PRESIDENT said that the papers were very valuable as giving fresh data for the diagnosis of these puzzling tumours. They did not strongly support the view that he had always held that these cysts were usually traumatic.—Dr. C. W. CHAPMAN had seen one case of pancreatic cyst of doubtful origin in a lad aged ten

[1] THE LANCET, Oct. 24th, 1896, p. 1149.

Digitized by Google

years. The cyst was incised and drained by the late Mr. Leopold Hudson and the patient was now in perfect health.—Dr. DE HAVILLAND HALL mentioned a case of pancreatic cyst in which jaundice was one of the first symptoms. As this did not clear up Mr. Pearce Gould cut down and found a cyst of the head of the pancreas.—Mr. BATTLE asked if there were any facts showing what liability there was to relapse and as to the efficacy of drainage from the loin. He mentioned a case that he had seen with Dr. Hector Mackenzie of enlargement of the liver, probably syphilitic, in which a swelling appeared in connexion with the head of the pancreas. As this did not disappear under iodide of potassium he explored and found a mass there the nature of which could not be ascertained, but it entirely disappeared and was probably gummatous.—Mr. DORAN, in reply, said that the hard material mentioned by one or two speakers as affecting the head of the pancreas was probably pancreatitis, in some cases possibly traumatic. A posterior incision had been adopted by Mr. Pearce Gould in his first case. He thought that the cyst removed by Mr. Malcolm very closely resembled the retro-peritoneal cysts, probably congenital, which were sometimes met with in front of the kidney.—Dr. ROLLESTON, in reply, said that in three fatal cases of acute pancreatitis which he had seen there had been localised effusion into the lesser peritoneal cavity. Possibly if they had recovered this effusion of fluid might have become encysted. Enlargement of the head of the pancreas might be due to malignant disease, but it was also common in any cases of inflammation about the pylorus or duodenum from localised pancreatitis, and Dr. Hale White had shown that the head of the pancreas might be so much enlarged as to be palpable in consequence of back pressure from cardiac valvular disease.—Mr. MALCOLM, in reply, said that the cyst in his case was very like the retro-peritoneal cysts referred to by Mr. Doran, but it was very closely associated with the tail of the pancreas and large vessels entered it from that body, so that he had little doubt that it was a true cyst of the pancreas.

CLINICAL SOCIETY OF LONDON.

Acute Intestinal Obstruction; Death from Intestinal Toxæmia.—Vesical Calculus as a Result of Injury of the Bladder during the Operation for Radical Cure of Hernia.—Cases of Intussusception.

A MEETING of this society was held on Dec. 10th, Mr. LANGTON, the President, being in the chair.

Mr. PEARCE GOULD read a paper on a case of Acute Intestinal Obstruction relieved by operation in which death occurred on the ninth day from Intestinal Toxæmia. The patient was a man, aged forty-three years, who developed symptoms of acute intestinal obstruction after receiving a strain at his work. On the fourth day the abdomen was opened and a coil of small intestine was found in the pelvis adherent and twisted on itself. This was liberated and at once the fluid intestinal matter passed into the collapsed lower ileum and cæcum. Next day a small motion was passed and two days later flatus passed freely and also a large formed motion showing that the obstruction was relieved. For three days after the operation intestinal matter regurgitated into the stomach and was removed by washing out the stomach on three occasions. The patient took fluid food well and there were no signs of peritonitis, but still the urine continued to give a very dark indican reaction with nitric acid and gradually he passed into a condition of stupor, deepening into coma, accompanied by a slightly quickened pulse, quickened, deep, and noisy respiration, a subnormal temperature which was lower in the rectum than in the axilla, profuse diarrhœa, the motions being of a peculiar odour and of a grey-green colour, and the skin was covered with a dark erythematous rash. These symptoms first reached their maximum on the sixth day after the operation; four pints of saline fluid were injected into a vein and immediately all the symptoms passed away. He relapsed next day and saline fluid was again injected with marked benefit. Two days later he again became unconscious and died comatose in spite of a third injection of salt and water. All this time the urine contained a great excess of indican and Dr. P. A. Young, who analysed the urine, found that another chromogen was present which was converted into dark brown pigment by [illegible]ation but was not melanin. Mr. Gould pointed out that [illegible]ymptoms were toxic and their slow onset, coupled with the marked instantaneous effect of saline infusion and the succeeding relapse, he took as showing the poison was a chemical one which only exerted its influence when in a certain degree of concentration.—Mr. A E. BARKER mentioned the case of a woman whose abdomen was opened in consequence of intestinal obstruction. The cause was a growth which could not be removed and intestinal anastomosis was performed. A few days afterwards she developed an erythematous rash which he believed was due to poisonous substances absorbed from the bowel.—Dr. P. A. YOUNG called attention to the toxic substances contained in normal urine which when injected into the blood caused acceleration of the heart, pyrexia, frequent micturition, and death.—Dr. COLMAN mentioned a case which was under the care of Mr. Grubb in which intestinal toxæmia caused not coma, as in the preceding cases, but mental excitement. The patient was a woman, aged about forty years, who had a large fæcal impaction in the ascending colon. Under treatment the mass became softer and she began to pass fæcal material in considerable quantity. But on the third day she became delirious with no knowledge of her surroundings, with hallucinations of hearing and hallucinations of vision which took the form of animals running about her bed, which did not terrify her but amused her. There was no history of alcohol or of the administration of belladonna. Her temperature was low and her pulse was quiet. By means of frequent enemata the bowel was completely emptied and the delirium entirely passed off. Dr. Colman remarked that erythematous rashes were not infrequently met with in children after the administration of enemata.—Mr. EASTES observed that in chronic cases there was often ulceration above the seat of the obstruction and it occurred to him that toxic substances might be absorbed through such a raw surface which would not penetrate the normal intestinal wall.—Mr. MAKINS asked whether the urine or the blood had been examined for micro-organisms. He thought that the rash was more likely to be of bacterial origin than due to chemical products. It was remarkable that the pulse should remain so steady if the condition was one of toxæmia.—Mr. GOULD, in reply, said that neither the blood nor the urine had been examined for micro-organisms. He thought that the evidence as a whole favoured the view that the condition was caused by a chemical poison rather than by living organisms.

Mr. LOCKWOOD described a case in which he performed Lithotrity for the removal of phosphatic calculi which had resulted from an injury to the bladder some months previously. The patient had been operated on in June, 1895, for the radical cure of a right inguinal hernia. He was, however, rejected for the army because of another incomplete inguinal hernia of the left side. In November, 1895, this was operated upon by Mr. Lockwood. Soon afterwards the patient complained of discomfort in the bladder and it was ascertained that at the first operation a finger-like extension of the bladder had been opened in dissecting away a mass of fat near the neck of the hernial sac. The opening had been closed by silk sutures. Pus afterwards appeared in the urine and a cystoscopic examination revealed the presence of two phosphatic calculi. Mr. Lockwood removed these by lithotrity and the patient soon recovered. No remains of ligatures could be found in the débris of the calculi. It was suggested that in future such injuries should be sutured with sterilised catgut inserted by Lembert's method.—Mr. BARKER asked whether there were many cases on record in which calculi had formed after ligature of the bladder in the ordinary way in consequence of the ligature forming the nucleus of a calculus. He had difficulty in understanding how the sutures should find their way into the cavity of the bladder.—The PRESIDENT said that hernia of the bladder was more frequent than was believed and was more common in men than in women and usually occurred on the right side. The relation of the peritoneum to the displaced organ was very variable. The etiology of the condition was obscure.—Mr. PEARCE GOULD related the case of a woman on whom he operated for a small swelling in the crural canal which proved to be a subserous lipoma. He dragged firmly on it, ligatured it, and cut off the end. Extravasation of urine followed and no doubt when dragging on the fat he had ruptured the bladder wall. Mr. Pearce Gould remarked that in this case the patient was a woman and the hernia was on the left side.—Mr. MAKINS thought that there was a tendency for any ligature in the pelvis to pass into the

Digitized by Google

bladder just as a ligature applied to the outside of the intestine usually found its way into the lumen of the bowel.—Mr. LOCKWOOD replied.

Mr. A. E. BARKER read a paper on Fifteen Consecutive Cases of Intussusception in eight of which injection failed, and subsequent events showed that no less than twelve of the fifteen could not possibly have been reduced by injection when first seen. He concluded, therefore, that except in the rare instances in which the case was seen within a few hours of the onset of the symptoms it is safest not to employ injections but to proceed at once to abdominal section.—Mr. LOCKWOOD said that after twenty-four hours the immediate performance of laparotomy gave the patient the best chance; after that time injection rarely did good and might do harm.—Mr. E. W. ROUGHTON said that his experience was limited to one case and in that he was able to open the abdomen within twenty-four hours of the commencement of the symptoms with a good result. The recorded cases appeared to show that the chances of recovery were in inverse proportion to the length of time that the symptoms had lasted and there were very few cases which recovered if the symptoms had lasted more than two days, and more recovered when operated on without previous injection than when injection had been tried, perhaps because of the delay involved.—Mr. BARKER, in reply, said that any liability to ventral hernia might be minimised by adopting a very small incision. In most cases an incision large enough to admit a single finger was sufficient. He should hesitate to draw conclusions from collation of isolated cases from the medical journals as only selected cases were published. A consecutive series of cases was more reliable and instructive.

OPHTHALMOLOGICAL SOCIETY.

Foreign Bodies lodged in the Eye and Orbit.—Mules's Operation for Ptosis.—Non-recurrent Orbital Sarcoma.—Solid Œdema of the Conjunctiva.—Traumatic Cyclitis.—Specimens of Pseudo-glioma.—Secondary Sarcoma of the Orbit.—Chip of Steel in the Vitreous for Eighteen Months.—Perforating Wound of the Eyeball.—Recurrent Membranous Conjunctivitis.

A CLINICAL meeting of this society was held on Dec. 9th, the President, Mr. H. R. SWANZY, being in the chair.

Mr. HARTRIDGE showed a case of Leaden Pellet lodged in the Eye, with skiagraph. The patient was shot in the right eye by a pellet from an air gun. When seen two hours after the accident there was a large linear wound of the cornea with prolapse of the iris and hæmorrhage into the anterior chamber. There was no perception of light. Tension – 1. The prolapsed iris was cut off. Two days later, after the blood in the anterior chamber had cleared up, it was found that the lens was wounded. A skiagraph was taken, the plate being placed on the right side of the head and the Crookes's tube on the left so that the x rays passed through the head from left to right. The exposure was fifteen minutes. The result showed that the pellet was lodged about the middle of the orbit. The eye was excised as it was obviously lost, and the pellet was found lodged in the globe.—Mr. J. F. BULLAR also showed a Skiagraph of a Fragment of a Percussion Cap in the Orbit.—Remarks were made by the PRESIDENT, Mr. BICKERTON, Mr. JOHNSON, Mr. TAYLOR, Mr. POWER, and Mr. HOLMES SPICER.

Mr. W. J. CANT and Mr. A. S. MORTON each showed a case of Ptosis treated by Mules's operation which consists in the insertion of a wire loop from the free edge of the lid beneath the skin to the eyebrow. Mr. Cant's case was one of congenital ptosis of one eye. When the frontalis muscle was put into action the lid was raised by means of the loop so as to expose the pupil. Mr. Morton's case was one in which ptosis had been present in the right eye for twenty years and in the left eye for three years. Referring to the difficulty of tightening the suture Mr. Morton had had a communication from Mr. Mules in which the latter said he used silver wire as stout as the lid would bear and before using it he heated it in a spirit lamp to make it less brittle. After inserting the suture from the free edge of the lid to above the eyebrow he allowed it to remain five or six days before tightening it. In order to tighten it the wire near the ends was grasped with lead-lined forceps while the ends were twisted. Mr. Morton had also heard from Dr. Tatham Thompson of his experience which was entirely favourable. In one of his cases after two months' use a blow on the eye caused the wire to snap but the ptosis was not so bad as it had been before insertion of the suture, a certain amount of cicatrisation of the subcutaneous tissue of the lid having been set up.

Mr. MORTON showed a case of Non-recurrent Orbital Sarcoma. The patient had had a sarcoma extending from the upper outer part of the orbit to its apex. The whole of the contents of the orbit were removed and chloride of zinc paste was applied. After fourteen months there was no sign of recurrence.

Mr. HOLMES SPICER showed a case of Solid Œdema of the Conjunctiva. The patient was a woman, aged twenty-one years. The condition was present in the right eye only; it was confined to the ocular conjunctiva; it had been noticed for about three or four months. The only apparent cause was an obstruction to the return of lymph from the eye produced by suppuration and subsequent cicatrisation in the lymphatic glands of the neck two years before. On the affected side the preauricular and cervical glands had both suppurated, and on the other side the cervical glands only. There was no proptosis of the eye; the vision was normal and the retina and its blood-vessels appeared normal. There was no sign of disease in the nasal passages.—The PRESIDENT thought the case was a very rare one.—Mr. ADAMS FROST thought it was similar to two cases shown at the society some years before by Mr. Donald Gunn which were described as syphilitic infiltration of the conjunctiva. In those cases he thought the preauricular glands were also enlarged.—Mr. SILCOCK referred to a case which he had published in the Transactions of the society similar to this one; he had incised the conjunctiva and scraped granulation tissue from Tenon's capsule.—Mr. EALES spoke of a case of similar appearance which he had seen.

Mr. MARSHALL showed a specimen of Traumatic Cyclitis, in which the injury had been caused by a piece of wood; there was a dense cyclitic membrane dividing the eye into two cavities.

Mr. MARSHALL showed one specimen of Pseudo-Glioma, and Mr. ERNEST CLARKE another. In the former the child was seven weeks old, there was a white mass seen behind the lens, and the tension of the eye was raised. After excision the case was found to be one of pseudo-glioma. Mr. Clarke's case was one of bilateral pseudo-glioma, in which there was a record of pseudo-glioma occurring in two other members of the family.—Mr. TREACHER COLLINS said that he would have been inclined, apart from the family history, to have regarded this as a case of congenital membrane in the vitreous.

Mr. RIDLEY showed a case of Secondary Sarcoma of the Orbit. There were all the signs of a tumour of the orbit, and there were also tumours of the scalp, of the supra-spinous fossa, and of one fibula.—Remarks were made by Mr. JESSOP, Mr. EALES, Mr. COLLINS, and Mr. NETTLESHIP.

Mr. LAWS showed a patient with a Chip of Steel in the Vitreous which had been there for eighteen months. There was no sign of irritation; the body in the vitreous was encapsuled; there were several red streaks on the lens and fine red particles all over the surface of the lens; the lens remained clear for fifteen months but had slowly become opaque in its posterior parts.

Dr. BRAILEY showed a case of Perforating Wound of Eyeball. The patient's right eye had been struck by a piece of wood. There had been a wound of the cornea and prolapse of the iris; the prolapse had been removed. Without any apparent cause the vision of the other eye which had remained quite good for two months and a half was beginning to deteriorate and had fallen from $\frac{6}{6}$ to $\frac{6}{18}$. There was no sign of sympathetic inflammation and nothing to account for the defect.

Mr. BATTEN showed a case of Recurrent Membranous Conjunctivitis. The membrane had been removed several times but always recurred; it had the appearance of a superficial burn. The bacteriological examination had not been completed.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.

Exhibition of Cases and Skiagrams.

A MEETING of this society was held on Nov. 11th, the President, Dr. DAVID FAIRWEATHER, being in the chair.

Dr. SCLATER JONES read the notes and showed Skiagrams

Digitized by Google

of a case of a child in whom a shilling had remained lodged in the cardiac end of the œsophagus for six months. The coin was successfully removed by an umbrella probang.

Dr. SYERS showed two cases of Lichen Ruber Planus in female patients aged thirty-four years and twenty-six years respectively. In the former the rash had been present for two months and in the latter for five months. The distribution in both cases was typical and both patients were in good general health.—Dr. SYERS also exhibited a well-marked case of Dermographia. The affection first manifested itself at the age of thirteen years and had existed for four years. The slightest injury or irritation of the skin produced marked erythema followed by the development of urticarial wheals and by a sensation of burning and tingling. There was no connexion between the diet and the appearance of the eruption. With the exception of a tendency to constipation the health had always been very good.—A fourth case shown by Dr. SYERS was a man, aged fifty-two years, from whose left pleural cavity several ounces of chylous fluid had been obtained. Dr. Syers expressed the opinion that it was a case of chylothorax due possibly to tuberculous or to malignant disease of the lung and pleura which had involved a portion of the thoracic duct.

The Secretary (for Dr. MALCOLM) showed a case of a child, aged ten years, who had been treated for Torticollis by division of both heads of the Left Sterno-cleido-mastoid through open Wounds. The patient was treated subsequently to the operation for six weeks by a traction apparatus made of plaster-of-Paris and pieces of drainage tube and now four and a half months after the operation there was no recognisable deformity.

Mr. CLEGG exhibited the following cases: (1) Tuberculous Disease of the Testicle in a child eleven months old—the vesicula seminalis of the same side contained a large deposit of tubercle; (2) a very pronounced case of Hallux Valgus; (3) a case of Syphilitic Arthritis of the Knee-joint; and (4) one of Extensive Tertiary Syphilitic Ulceration of the Lower Limb.—Dr. CLEGG also showed a specimen of Black Urine from a patient who had swallowed four ounces of Calvert's No. 5 carbolic solution.

Mr. GORING and Mr. MOWER WHITE showed a female patient, aged fifty-three years, who was admitted to the hospital suffering from the effects of a gumma of the cerebral cortex involving the upper limb "area." Jacksonian fits followed by dementia and signs of cerebral compression occurred after admission and to relieve these symptoms a large piece of very dense and greatly thickened bone was removed. The dura mater, which was involved in the gumma, was not opened. The improvement immediately after the operation was very marked and subsequently large doses of iodide of potassium led to recovery.

The PRESIDENT, Dr. BAILEY, and others took part in the discussion which followed the exhibition of each case.

MANCHESTER MEDICAL SOCIETY.

Exhibition of Cases.—Henoch's Purpura.

A MEETING of this society was held on Dec. 1st, Dr. GRAHAM STEELL, President, being in the chair.

Dr. ERNEST S. REYNOLDS showed the Photograph of a man, aged thirty-five years, suffering from typical Pseudo-hypertrophic Paralysis with well-marked enlargement of various muscular groups.—Dr. REYNOLDS also showed a boy, aged eighteen years, who was the son of the sister of the above patient. This boy also was suffering from the same disease, but at first sight without enlargement of the affected muscles. More careful examination showed, however, that the calves, the buttocks, the deltoids, the forearm muscles, and especially the infraspinati were enlarged and increased in hardness. All these groups of muscles were very weak and the patient had the typical "waddling" gait. The facial muscles were unaffected.

Mr. J. E. PLATT showed a patient, a young woman, aged nineteen years, who had had almost the whole of the scalp torn off as a result of a machinery accident in July, 1896. The detached portion had extended from the occipital protuberance to within one inch of the forehead. The raw surface was afterwards covered up by Thiersch's method of skin-grafting which was carried out in two stages at periods of a month and six weeks after the accident respectively. Three months after the injury the whole surface was healed. Twelve months later the grafted surface remained quite sound and had regained a considerable degree of tactile sensibility. The patient almost invariably gave correct answers when asked whether any part of the scalp was being touched and there was very fair power of recognising two points as distinct when the scalp was touched in two places a short distance from each other. The method of performing the operation, the precautions necessary to ensure success, and the cases which are suitable for this method of treatment were briefly alluded to.

Dr. DRESCHFELD made some observations on the symptoms, pathology, and treatment of Henoch's Purpura, cases of which, though not under this name, have been repeatedly observed and described in English journals. The disease occurs much more frequently in children and the principal symptoms are: (1) pain in and near a joint; (2) a purpuric or erythematous eruption; (3) abdominal pain accompanied by vomiting and diarrhœa; and (4) hæmorrhagic nephritis. In typical cases all these symptoms are present; in other cases one or other of the symptoms may be absent. Relapses are very common. Referring to each group of symptoms it must be noted that the pain is often the first symptom noticed; it is often only slight and transient and may affect larger and smaller joints; often there is also some œdema near the joint. The skin eruption occurs early in the disease and may take the form of erythema nodosum, erythema circinatum, or urticaria; hæmorrhages in the affected patches may take place and lead to sloughing ulcers; purpuric spots may appear on the lower and upper extremities and on the face; these eruptions may last for some days, then disappear and reappear; this may occur several times. The gastro-intestinal troubles occur often at a later period and resemble very much the gastric crisis of locomotor ataxy. The vomiting may be very persistent, the vomited matter consisting of mucus and bile; at other times blood is vomited. Diarrhœa may be present and become troublesome and the stools contain blood; the abdominal pain is often very severe; the patient feels quite exhausted and may even become collapsed. Hæmorrhage from the kidney has been noticed in all the nine cases observed by Dr. Dreschfeld and appears to be very common in this disease; the urine beside the blood shows hyaline, granular, and epithelial casts; often after the hæmaturia stops the urine still contains for weeks albumin and casts; relapses of the hæmaturia are not uncommon. Besides the hæmaturia other hæmorrhages (epistaxis, hæmoptysis, retinal hæmorrhages, melæna, &c.) have been noticed. The temperature may be normal throughout the disease, but occasionally there is remittent or intermittent pyrexia. The spleen in several of the cases observed was found to be slightly enlarged. Endocarditis, pericarditis, and pneumonia have occasionally been observed as complications. The prognosis is on the whole favourable. Death may take place from the excessive renal hæmorrhage, or from cerebral hæmorrhage, or from acute uræmia; some cases pass into chronic Bright's disease as described by Osler. Quinine has been found very useful and turpentine has in several cases checked the renal hæmorrhage effectively. In a case published by Sansom with very severe hæmorrhage the patient recovered after the administration of half-drachm doses of sulpho-carbolate of soda. The disease belongs to the group of purpuric diseases and is probably due to a bacillus, as shown by the observations of Letzerich, Tizzo, Babes, and others. Bacteriological examination of the blood in two cases observed by Dr. Dreschfeld gave negative results.—Dr. EDGE made some remarks on the disease which has been described by Mr. Hutchinson under the name of "gouty hypertrophic acrodermatitis" and of which Dr. Crocker in conjunction with Mr. Campbell Robinson has published a case under the title of "erythema elevatum diutinum." He also showed a girl, aged eighteen years, who presented the disease in a well-marked form. He referred more particularly to cases occurring in young people which both these writers consider to constitute a type more or less distinct from those found in men past middle life. Dr. Edge said that his case strongly supported the suggestion of Dr. Judson Bury, who was the first to record a case in a young person, that this disease is a disturbance of nutrition due to altered innervation of the vaso-motor system.

Dr. ARTHUR HELME mentioned a case of Acute Ascending Paralysis during Lactation.

LIVERPOOL MEDICAL INSTITUTION.

Changes in the Spinal Cord.—Exhibition of Specimens.

A MEETING of the Pathological Section was held on Dec. 9th, Mr. F. T. PAUL being in the chair.

Dr. A. W. CAMPBELL read a note on the Changes in the Spinal Cord in Pernicious Anæmia. The patient was a middle-aged female. The spinal cord in the sacral region was healthy. In the lower part of the lumbar enlargement two small patches of absolute sclerosis appeared in the centre of the posterior columns, one on either side of the posterior median fissure. In the dorsal region the field of sclerosis gradually increased in size, but remained more or less confined to the postero-internal columns, the whole of which it affected with the exception of a zone of fibres at the periphery and another zone adjoining the posterior commissure. In the cervical region the change was most extensive, not only the postero-internal, but also to a certain extent the postero-external columns being involved. As in the dorsal region, the sclerosis was separated from the periphery and from the grey commissure by a zone of normal fibres and at no point in the cord did the sclerosis reach the posterior cornua. The remaining fields of the cord were healthy. The sclerosis was traced up to the nuclei of the columns of Goll and Burdach, but the cells of these nuclei had undergone no important change nor were the internal arciform fibres atrophied. The posterior spinal roots and some posterior root ganglia and peripheral nerves which were examined presented no noteworthy alteration. The literature on the subject was referred to and theories concerning the origin of the spinal change were discussed. A lantern demonstration was given and microscopic specimens were shown.

Dr. WIGLESWORTH showed the following specimens:—1. Acute Pancreatitis. The investing tissues were thickened and brawny and the pancreas itself was enlarged, of a pale yellow colour, with diminished consistence, and microscopically there was great proliferation of small round cells alike in the investing tissues, along the trabeculæ and between the alveoli. The cells of the alveoli were blurred and in osmic acid preparations were laden with coarse black pigment granules. The gall-bladder was inflamed and contained fœtid semi-purulent fluid, but no other organ of the body was diseased. The specimen was taken from a man, aged fifty-three years, who died after two days' acute illness with vomiting, abdominal distension, and rapid collapse. 2. Hæmorrhage into the Pancreas. The pancreas was somewhat enlarged and acutely reddened for the middle third of its extent, which area was found on microscopical examination to be the seat of a sanguineous effusion beneath the capsule and along the trabeculæ. There were, in addition, several hæmorrhages consisting of black blood clot, each about 1 c.m. in diameter; these were situated beneath the capsule, chiefly towards the head of the organ. There were numerous hæmorrhages into the omental fat around the pancreas and also numerous areas of fat necrosis. The specimen was taken from a female general paralytic, aged thirty-seven years, who died after about three days' illness, with urgent vomiting, constipation, abdominal distension, and collapse. 3. Lymphadenoma of the Spleen. The spleen was enlarged to about three times its normal size, weighed fourteen and a half ounces, and exhibited scattered throughout its whole substance numerous whitish nodules varying from the size of a bean to that of a small shot, which were of very firm consistence. There were similar nodules in both lungs and the retro-peritoneal and mesenteric glands were much enlarged. The specimen was taken from a female, aged thirty-eight years, who had been gradually wasting and suffering from fever both of continuous and hectic type for several months.

Dr. J. HILL ABRAM described and exhibited a new Micro-organism which he found in the blood of a patient suffering from lymphadenoma.

Dr. J. E. DUTTON read a note drawing attention to the marked increase in the quantity of Iron in the Liver and Spleen in cases of malaria, there being five times the normal amount in the liver and ten times the normal amount in the spleen in two cases examined by him.

The following specimens were also exhibited:—

Dr. BRADSHAW: Tuberculous Suprarenals from a case of Addison's Disease.

Mr. KELLETT SMITH: Fibroma with Silk Ligature as Nucleus

Dr. WARRINGTON: Sarcomatosis of Ovary, Thyroid, Kidney and Intestine from a child.

Mr. NEWBOLT: (1) Carcinoma of the Tibia (Secondary?); and (2) Multiple Neuromata.

Mr. RUSHTON PARKER: Carcinoma of the Male Breast, Stomach, and Lymph Gland; Tuberculous Peritonitis, Macroglossia, and Nævi of Ear and Scalp.

Mr. THURSTAN HOLLAND: Radiographs.

Dr. BUCHANAN: Pinguecula (Epithelial).

Mr. F. T. PAUL: Sections of Early Human Embryos showing stages in the development of the Wolffian body.

Mr. PAUL, Professor BOYCE, Dr. WARRINGTON, Dr. BRIGGS, and Dr. LOGAN took part in the discussion.

MANCHESTER PATHOLOGICAL SOCIETY.

Exhibition of Specimens.

A MEETING of this society was held on Dec. 8th, Mr. C. E. RICHMOND, President, being in the chair.

The PRESIDENT showed: (1) a preparation of Myxo-Sarcoma of the Femur; and (2) a Mixed-celled Sarcoma apparently arising from the Antrum. This had given rise to tooth trouble and several teeth had been extracted. This procedure was immediately followed by rapidly growing tumours on the alveolus. The upper maxilla was excised but it was found impossible to remove all the new growth which rapidly recurred and the man died within a month of operation.

A rare and interesting specimen of Congenital Dilatation of the Colon was shown by Dr. A. T. WILKINSON.

A specimen of Molluscum Fibrosum and Fibro-lipoma of the Arm removed by Mr. Walter Whitehead was described by Mr. RAY, who pointed out that the growth extended from shoulder to wrist, and was almost entirely on the extensor surfaces. The main portion of the tumour depending from the forearm was coarsely ridged and pitted and had several degeneration cavities and one large suppurating cavity. On the inner and outer borders of the forearm were several pedunculated fibromata, which were shown to be connected with two of the cutaneous nerves of the forearm. From the shoulder to elbow, apparently independent of the molluscum growth, was a large fibro-lipoma. The entire limb weighed seventy and a quarter pounds immediately after operation, and the patient made a good recovery. The structure of several parts of the tumour was described and illustrated by micro-photographs, whilst another set of photographs was exhibited to show the patient, a male, thirty-two years of age, before and after operation. The growth was first noticed at about the age of seven years, the patient having sustained a fracture of the radius and ulna of this limb eighteen months previously. He presented no other growths elsewhere.

Dr. NATHAN RAW (Liverpool) described the pathological appearances and showed macroscopical and microscopical specimens of a Lung in which the Pleura was the seat of Acute Tuberculosis without any invasion of lung tissue. Very many and interesting points were suggested by this case, chiefly the etiology of pleurisy and the treatment of tuberculous pleurisy. Modern views did not admit pleurisy as due to cold, but cold might be a predisposing agent which facilitated the action of micro-organisms. If cold was the only cause of pleurisy a very large number of people who are constantly exposed to cold and wet would suffer from it. Dr. Raw thought the evidence at the present time all points to the fact that acute sero-fibrinous pleurisy is always of microbial origin, in a very large number of cases due to the tubercle bacillus, and in others occurring in the course of rheumatism, septicæmia, or other infectious diseases due to specific micro-organisms. The importance of carefully recognising the subsequent relation of acute pleurisy to tuberculosis of the lung is very great and especially so with regard to examining patients for life insurance. Dr. Raw also recommended that as much of the infected pleura as possible should be removed and scraped away under operations for empyemata which have been recognised as tuberculous.

Dr. PERCY R. COOPER and Dr. KELYNACK showed preparations of Syphilitic Disease of the Right Kidney. The specimen was removed post-mortem from a man, aged

Digitized by Google

fifty-two years, who died after a long illness in which the most conspicuous symptoms were vomiting, neuralgic pain in the nerves of the right lumbar plexus, hæmaturia, wasting, and progressive enlargement of the kidney. No syphilitic history could be obtained. The organ was greatly enlarged, firmly fixed, of fibrous-like consistency, and microscopically presented a fibro-cellular structure. In the liver was a distinct gumma with much coarse cirrhosis in the parts adjacent. There was an extensive retroperitoneal expansion of the growth extending right across the vertebral column and into the pelvis.

Dr. KELYNACK exhibited a series of microscopic preparations illustrating the Forms and Relationships of the Various Growths met with in the Kidney. The collection included a number of specimens kindly lent by Mr. Paul, of Liverpool.

The following card specimens were exhibited :—

Mr. BURGESS: Congenital Absence of Anus, with Fistulous Communication between Rectum and Bladder.

Dr. DRESCHFELD: Mediastinal Sarcoma, with extensive Deposits in both Kidneys.

Dr. FOTHERGILL: (1) "Inclusion" Epithelioma of enamel-organ; and (2) Ovum in Condition of Fatty Degeneration.

Dr. FOX: (1) Congenital Atresia of Anus; and (2) Ulcerative Endocarditis.

Dr. HELME: Sessile and Pedunculated Submucous Fibroids of Uterus, removed per vaginam.

Dr. HARRIS: Gangrenous Stomatitis.

Dr. KELYNACK: (1) Perforated Duodenal Ulcer; (2) Healed Gastric Ulcer; and (3) Malignant Endocarditis.

Dr. LEA: (1) Series of Casts of Uterine Mucous Membrane; and (2) Three Specimens of "Missed Abortion."

Dr. LEECH: Unusual Form of Extensive Ulceration of Stomach.

Dr. STEELL: Preparations of Aortic Valvular Disease.

Mr. WOLSTENHOLME: Aneurysm of Renal Artery in the Horse.

Mr. WRIGHT: Osteomyelitis of Femur.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.—Serum Reaction of Enteric Fever.—Cyanosis in Convulsions.

A MEETING of this society was held on Dec. 1st. Dr. BATTY TUKE occupied the chair and thanked the society for the honour it had done him in electing him President.

Dr. J. W. MARTIN showed a case of Thyroid Hypertrophy with aggravated symptoms, which had been markedly benefited by the use of splenic and thymus extracts.

Dr. ALLAN JAMIESON showed two patients with Eczema Palmare which had been successfully treated.

Mr. ALEXIS THOMSON showed (1) a Hydatid Cyst which he had removed from the liver; and (2) a portion of Gangrenous Intestine, the result of strangulation by a band, which he had removed.

Dr. HARVEY LITTLEJOHN showed specimens from (1) three cases of sudden death due to rupture of an aortic aneurysm in none of which had the diagnosis been made before death—in one of the cases there had been a history of blood-spitting for two years; and (2) a case of Rupture of Tubal Pregnancy, in which there had been profuse hæmorrhage into the abdominal cavity, the rupture having been the result of an injury to the abdomen.

Mr. COTTERILL showed (1) specimen from a case of Enterectomy for Fibrous Stricture—the operation had taken three hours to perform and the patient was doing well; and (2) a specimen of Perforated Appendix which had been removed. The patient did well for some days, after which the symptoms returned, and on re-opening the abdomen the stump of the appendix was found to have sloughed off. The patient was again progressing satisfactorily.

Dr. AFFLECK demonstrated an adaptation of the Phonendoscope for teaching purposes. By attaching tubing twelve feet long it was possible to demonstrate heart murmurs to members of the class at that distance from the patient.

Dr. CLAUDE B. KER read a paper on the Serum Reaction of Enteric Fever. Dr. Ker's paper was based upon work during the current year in the Edinburgh Fever Hospitals. As regards his method of investigation he used blood serum in the dilution of 1 in 30 of beef bouillon. His rule was to give the specimens a time limit of four hours. If at the end of that time the clumps were not distinct and the field between them clear he considered the reaction negative. If there was a partial clumping he waited for a few days and then examined another specimen of the patient's serum. The cases examined were cases sent into the hospital as enteric fever or for observation for enteric fever and were 169 in number. Of those cases which gave the reaction there was one which Dr. Ker did not believe to be enteric fever. It was apparently a case of typhus fever. Of the cases showing negative result with the serum test there were three which were possibly enteric fever. Those four cases were the only ones in which the results obtained were dubious. Dr. Ker therefore concluded that Widal's test might be accepted as the best method for the diagnosis of enteric fever. He had found that the age of the patient in no way interfered with the reaction, his youngest patient having been one year and his oldest fifty years of age. He had also found that capsules of dried bacilli gave results that were entirely satisfactory. In conclusion he emphasised the fact that to obtain good results it was necessary that the serum should be sufficiently diluted. He had always endeavoured to have it at 1 in 30 though 1 in 25 was probably sufficient. One drop of blood was drawn up into a pipette and then sterilised beef bouillon was sucked up till there was a mixture of one of serum in ten of bouillon. This after centrifugalisation was further diluted by adding the bacteria as an emulsion in bouillon which brought the serum to the desired proportion of one in thirty.

Dr. FOULIS read a paper on Cyanosis in Convulsions; how Caused and how Prevented. He demonstrated very vividly that the cyanosis was the result of the base of the tongue falling against the posterior wall of the pharynx and thus mechanically obstructing the entrance of air. He illustrated this by means of limelight views taken from frozen sections made by Symington and others. He pointed out the disadvantages and the inefficiency of pulling the tongue forward in these cases. He advocated a method which he had employed for many years and found most efficacious. He introduced the handle of a spoon far back in the mouth and by means of it compressed and brought forward the root of the tongue. By this means air was allowed freely to enter the lungs. He had used the method not only in the convulsions of children but also in the threatened cyanosis which was liable to occur in cases of cerebral apoplexy.

FORFARSHIRE MEDICAL ASSOCIATION.

Bradycardia.—Abdominal Cases.—Exhibition of Cases.

A MEETING of this society was held on Dec. 3rd in the University College, Dundee, Dr. J. W. WEMYSS, Broughty Ferry, ex-President, being in the chair.

Dr. TENNANT BRUCE read notes of a case of Bradycardia. The pulse varied from 20 to 34 per minute and was associated later with convulsions of an epileptiform character. The literature of the subject was reviewed. Dr. Bruce suggested that some confusion existed due to confounding two distinct conditions—viz. (1) slow pulse as a symptom of other diseases and (2) slow pulse as a disease itself and dependent on interference with nerve force. Though interference in the functional activity of the intrinsic cardiac ganglia was, he thought, the most probable explanation, yet the possibility of a purely medullary origin must not be lost sight of. He quoted the position of the intra-medullary nuclei given by Dr. Alexander Bruce in his book on the Hind Brain and asked whether lesion in the neighbourhood of the motor nucleus of the vagus, the nucleus ambiguosus, might not explain the condition.—Dr. SINCLAIR agreed with Dr. Bruce that slow pulses after influenza or other diseases should be excluded and quoted a case similar to that given by Dr. Bruce in which a cessation of pulse-beat preceded epileptiform convulsions.

Mr. GREIG read notes of two Abdominal Cases. The first was a case of Enterectomy with end-to-end Anastomosis. The patient, aged sixty-nine years, was admitted to the surgical wards of the Dundee Infirmary suffering from strangulated inguinal hernia on the right side. There was a small irregular laceration found in the portion of bowel exposed; this was excised and the cut ends of the bowel were

Digitized by Google

brought into apposition and sutured. The patient recovered well from the operation, had no pyrexia, and left the infirmary in four weeks wearing a truss. Mr. Greig considered this operation preferable, though it occupied a little longer time, to the introduction of a foreign body such as Murphy's buttons or bobbins. The second was a case of Intra-abdominal Strangulation successfully treated by Cœliotomy. The patient was a stout, healthy boy twelve years of age who was admitted into the infirmary with symptoms of acute obstruction. On opening the abdomen there was found to be distension of the small intestine and of part of the large intestine. There were several enlarged glands but one larger gland to which the omentum was adherent and also an appendix epiploica which had caused kinking of the bowel. This was divided and the obstruction relieved. The patient was restless and for this reason required to be dressed daily. The stitches were removed on the tenth day but were reintroduced under chloroform because the boy was so restless as to open up the wound and allow the bowel to prolapse. The case gave no further trouble, and the patient was dismissed in due course. Mr. Greig thought this showed a tolerance in succeeding cœliotomies — Mr. GREIG also showed a photograph of a case of Recovery from Favus of six years' duration, the treatment being daily depilation and inunctions with various parasiticides for twelve months.—Dr. WHYTE quoted cases of recovery under similar treatment.

Dr. KYNOCH showed a case of Dermatitis due to Pregnancy.

Mr. GREIG showed (*a*) Hæmatoma removed from the neck, (*b*) Congenital Dislocation of the Humerus, and (*c*) Cast of Osteo-arthritis of the Wrist and Ankle from a lad of thirteen years.

Dr. WHYTE showed an Aneurysm of the Aorta involving the ascending, transverse and descending portions of the aorta.—Dr. WHYTE also showed a Liver from a woman, aged fifty-three years, who had had symptoms of obstructive jaundice. There was a large caseating gland surrounded by a dense mass of fibrous tissue involving the hepatic duct. There was also some perihepatitis with several small abscesses throughout.

Reviews and Notices of Books.

A Manual of Midwifery. By ALFRED LEWIS GALABIN, M.A., M.D. Cantab., F.R.C.P. Lond., late President of the Obstetrical Society of London; Obstetric Physician and Lecturer on Midwifery and the Diseases of Women to Guy's Hospital, &c. Illustrated with 271 Engravings. Fourth edition. London: J. & A. Churchill. 1897. Price 15*s.*

THE appearance of this, the fourth, edition of Dr. Galabin's "Manual of Midwifery" sufficiently indicates its continued popularity. The work has been thoroughly revised and a few new illustrations have been added. The section on the structure of the chorion and the placenta has been brought up to date. One of the new illustrations shows the appearance of the chorionic villi in section from an ovum at the sixth week. The author says: "In a well-preserved specimen of a young placenta a double layer of cells may be demonstrated covering the villi and all other parts of the chorion. After the mid-term of gestation the deep layer disappears more or less completely. In a full-term placenta even the superficial layer has disappeared from many of the villi and the fœtal capillaries are only separated from the maternal blood-space by a delicate layer of connective tissue. The superficial layer consists of a thin stratum of granular multi-nucleated protoplasm in which no cell outlines can be distinguished. This layer has been called by some the 'syncytium.' In the deep layer the cells are large and well defined with oval nuclei standing with their long axes at right angles to the surface."

In the chapter on Extra-uterine Fœtation we see that the author does not regard all ectopic pregnancies as primarily tubal, in which he differs from the majority of modern authorities. Dr. Galabin is of opinion that a primary abdominal fœtation is a thing that does actually, though rarely, occur. His retention of this variety (primary abdominal fœtation) in his classification seems to be chiefly based on a case that occurred in his own practice, but even in that case he admits the possibility that it might have been an example of tubal abortion. In describing the treatment advisable in Accidental Hæmorrhage the author says: "The membranes should be punctured as soon as possible. ..... Plugging the vagina is considered inadmissible in cases of accidental hæmorrhage because concealed hæmorrhage might be going on behind the plug. ..... It is important for the student to remember the correct treatment of accidental hæmorrhage not only for the sake of his patients but because a question on this subject is frequently a fatal one in examination especially if plugging the vagina be suggested as treatment." Possibly the author may not have seen Dr. Jellett's little book on Midwifery recently reviewed in these columns. In a prefatory note to that work Dr. Smyly, speaking of his experience of rupturing the membranes in serious cases of accidental hæmorrhage, says: "The results were so bad that I resorted to plugging in all cases of external accidental hæmorrhage in which the membranes were intact and labour pains absent or feeble—that is, in the great majority of cases—and with excellent results. The fear that an external would be converted into an internal hæmorrhage proved groundless." We should like to have seen this aspect of the matter thoroughly discussed by an obstetrician of Dr. Galabin's experience.

We have no doubt that the present edition will be received with as much favour as its popular predecessors.

The Journals of Walter White, Assistant Secretary of the Royal Society. With a Preface by his brother, WILLIAM WHITE, and a Portrait. London: Chapman and Hall. 1898. Price 6*s.*

A PERUSAL of these journals reminds the reader of Pepys's Diary. We find the personality of the author reflected just as clearly in the earlier entries, during the time when he pursued his calling as a cabinet-maker, as in the latter records, made when he was Assistant Secretary of the Royal Society, the spirit of the student pursuing knowledge for its own sake, so characteristic of the author, being very apparent. The entry of Jan. 30th, 1837 ("Reading, writing, working at washstand *au soir*, much pleased with the book I have, showing knowledge may be acquired in spite of adverse circumstances. Ought I not to apply myself also?"), when coupled with that of Oct. 10th, 1870 ("Everything confirms my opinion that what is wanted is not more appliances for education, but students who really are in earnest") afford an interesting instance. Many other entries showing the same excellent philosophic temper will be found. Greater interest will attach to those descriptions and incidents in the lives of prominent personalities of the century with whom Walter White was brought in contact while at the Royal Society. The friendship existing between the author and the late Poet Laureate is dealt with in a separate chapter. The poet's passion for tobacco is well illustrated. The entry of Oct. 16th, 1852, records: "Tennyson came to the library to-day. After a time he said, 'I must have a pipe,'" and apparently he was referred to the roof. So the entry concludes: "In a quarter hour he came down again greatly refreshed." A very interesting conversation between Kingsley and Carlyle is recorded. In reference to preaching Kingsley spoke of 15,000 clergymen having to stand up Sunday after Sunday with nothing to say, adding, "Ah, the Reformation has much to answer for." Turning to Carlyle: "You and your Puritans have much to answer for. Those men first started the notion that the way to heaven was by infinite jaw, and see what infinite jaw has brought us

Digitized by Google

to." "Ay," said Carlyle, "'tis wonderful how men will go on talking with nothing to say." These are only a few of the numerous interesting little sidelights on the literary and scientific worthies, living and dead, including Huxley, Darwin, Lyell, Tyndall, Faraday, &c., to be found in the journal. The book should be warmly welcomed by scientific men.

Elements of the Comparative Anatomy of Vertebrates. Adapted from the German of Dr. Robert Wiedersheim by W. N. PARKER, Ph.D. London: Macmillan and Co. Price 12*s.* 6*d.*

THIS is the second English edition of Professor W. N. Parker's adaptation of Dr. Wiedersheim's well-known work. On comparing it with the former edition it will be noticed that a considerable amount of new material has been added, while many of the old figures have been replaced by others which are often more instructive as well as more artistic. The work may now be fairly described as profusely illustrated and we cannot help feeling sorry that it was not possible to enlarge the whole book somewhat in order to spread out the mass of facts with which it is filled. The determination to increase the number of illustrations and to add to the mass of facts without at the same time materially enlarging the size of the book has necessarily resulted in the matter being too condensed for an altogether satisfactory student's text-book. The condensing process, too, has not acted quite evenly, the skeleton obtains rather more than 100 pages for its description, while the muscular system is dismissed in ten pages. The liver of vertebrates is treated in three pages which, by the way, are chiefly occupied by illustrations and the pancreas takes up rather less than half a page. The last ninety pages of the book are devoted to a bibliographical appendix which in the places tested by us was found to be accurate and quite full enough for ordinary purposes.

The paper and printing are excellent and we have already expressed our opinion on the general value of the illustrations—a value that is added to by the fact that every part of each figure is clearly indicated and named without troubling the reader to seek an explanation on another page. There can be no doubt that this book should find a place on the shelves of every worker at vertebrate morphology.

JOURNALS AND REVIEWS.

The Ophthalmic Review. Edited by Messrs. LAWFORD, MACLEHOSE, and Others. London: J. & A. Churchill. Vol. XVI. Nos. 187–192.—These parts contain several interesting original communications. Amongst others are the following: Dr. A Alt on the histology of a case of sudden blindness caused by a gunshot injury to the skull. In this case the eye was not struck by the shot, but rupture of the choroid and detachment of the retina occurred from contre-coup with extensive hæmorrhage into the orbit necessitating removal of the eye and enabling a good histological examination to be made. Mr. C. G Lee describes a case of Malignant Tumour of the Orbit in which partial removal was accomplished followed by re-growth and, after the exhibition as a medicine of a decoction of cinnamon, complete recovery. The question whether cinnamon possesses any virtue as an antidote against malignant disease is thus raised. Dr. Jehin-Prume, of Montreal, contributes a valuable article on the proceedings and instruments to be employed when intravenous injections of mercury are practised and it appears that M. Wolfing-Luer, of Paris, has devised a syringe which is constructed wholly of glass and which works well whilst it is capable of easy sterilisation. Mr. Priestley Smith writes on Diminished Secretion as a Factor in the Causation of Primary Glaucoma, a view which he supports by reference to various well-known facts. Mr. Simeon Snell recommends the employment of Electrolysis as a Means of Treating Granular Lids. He gives the details of a convenient instrument for the application of electrolysis. The subject of Myopia is dealt with by Mr. W. G. Laws who reports a case of temporary myopia following a blow on the eye, and by Dr. Norman Maclehose who gives some notes of a myopic family. Dr. George Bull contributes an article on the Ophthalmometer as a Guide in Subjective Optometry. Mr. Myles Standish strongly insists in another article on Diphtheritic Conjunctivitis on the necessity of having a bacteriological diagnosis, since there is clinical evidence to show that this disease may be present in localised areas and that rapidly progressing ulcers of the cornea may be due to infection with the Klebs-Löffler bacillus and are then favourably affected by antitoxin treatment. Dr. Burnham gives the results of his Clinical Experience with Pilocarpine used hypodermically. In his hands when employed alone and in combination with other remedies it has proved successful in cases of rheumatism and of syphilis. Dr. Stevens, of New York, points out in a short article the relations which the Form of the Skull bears to the Occurrence of Trachoma. Dr. J. W. H. Eyre reports some cases of Albuminuric Retinitis and Dr. F. Buller has some notes on Mules's Operation. From an examination of these original articles, many of which are of considerable interest, it will be seen that the high position of the journal is fully maintained. The parts also contain various reviews and notices of books.

Recueil d'Ophtalmologie. Sous la direction de MM. GALEZOWSKI et CHAUVEL 3e. Série., 19. Année. Août Septembre, et Octobre. 1897.—This review, which is amongst the most important of the French journals on ophthalmology, contains in the last three parts that have been issued various papers of interest, amongst which are the following articles. M. Galezowski on Sympathetic and Parenchymatous Keratitis of the Cornea. Such forms of keratitis, he points out, are often complicated with iritis and resemble syphilitic keratitis, they may proceed from lesions of the opposite eye and from carious teeth and should be treated by removal of the exciting organ. Dr. Augiéras on the Stereoscopic Fusion of Colours. Dr. A. Puech on the Best Mode of Operating on Old and Large Fistulæ of the Lacrymal Sac. Dr. Vian, in an article on the Treatment of Purulent Ophthalmia both in Infants and in Adults, recommends the use of concentrated solutions of permanganate of potash. Dr. Strzeminski reports a case of Recurrent Paralysis of the Third Nerve and gives references to many other cases. Dr. Georges Valois gives the details of a case of Infective Ulcer of the Cornea and Dr. H. Bentejac one of Superficial Rodent Ulcer of Paludal Origin following an Operation. M. Pean describes the Surgical Treatment that should be adopted in cases of Exophthalmic Goitre. He considers that surgical treatment should only be resorted to when other means have had a fair trial given to them and have failed, but that the removal of the thyroid gland may be effected whilst the enlargement is yet of small size and that myxœdema is rare as a consequence of the operation and when it does occur is of transitory character. M. Bourgeois of Reims gives the treatment he has found successful in cases of Detachment of the Retina, which consists in the injection of ten drops of a fluid containing ten grammes of glycerine, three grammes of sodium chloride, and 0·001 gramme of perchloride of mercury. His results are excellent. M. Truc supplies a contribution from a clinical point of view to the Pathogeny and Treatment of Dry Blepharitis. The successive numbers contain full accounts of the meetings of the Société d'Ophtalmologie de Paris, reviews, and notices of books.

The December number of the *Veterinarian* is quite up to the average as regards the quality of its contents, whilst it is

Digitized by Google

larger than usual. The number consists of 134 pages and contains much valuable matter. The record of the Penycuik Experiments on Telegony and the Observations on the Striping of Zebras and Horses and on Reversion (Atavism) in the Equidæ by Professor Cossar Ewart is continued and a series of most interesting facts are brought out. This is followed by an article on Louping Ill and its Connexion with the Tick, by Alexander Meek, M.Sc., and R. Greig Smith, M.Sc., who have made a number of experiments on this question following up those already recorded by them. They draw attention to the fact that it is possible that some antitoxic method of serum treatment may yet be devised or discovered for the treatment of this disease as has already been done in the case of Texas fever and the tick fever in Australia. There are a number of interesting reviews and sixty-four pages of reports on veterinary medical societies from which it may be gathered that these societies are in an exceedingly flourishing condition. The papers reported are certainly full of interest and the discussions are in many cases somewhat animated. Altogether this is an exceedingly good number of the *Veterinarian*.

CHRISTMAS BOOKS.

MESSRS. CHAPMAN AND HALL have sent us the following:—1. *Four Poets: Selections from Wordsworth, Coleridge, Shelley, and Keats.* Selected by Oswald Crawfurd. Selections from any author are always apt, as Mr. Crawfurd candidly confesses in his preface, not to include the very passage or work that any particular reader happens to like best. We think, however, that the editor of this collection has been happy in his selections, for besides the well-known and generally appreciated poems he has given us some veritable gems much less commonly quoted; for instance, the magnificent lines of Shelley beginning, "Oh, world! oh, life! oh, time!" and the lines of Wordsworth on the expected death of Fox. The book is tastefully printed and bound and its price is 3*s.* 6*d.*—2. *Epigrams and Epitaphs.* Selected by Aubrey Stewart. Cloth, 2*s.* A charming little anthology. The flowers in the fields of epigram and epitaph are so many that it is difficult to make a really representative collection which shall form a nosegay of reasonable size, but Mr. Stewart has done his work well. We are tempted to quote a modern epigram which does not appear in this collection and which is, we fancy, not so well known as it deserves to be—one written by a former master at Eton on the occasion of a Mr. Day marrying a Miss Week:—

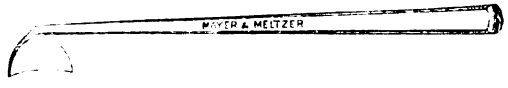
> "A Day the more, a Week the less,
> Yet Time must not complain;
> There'll soon be little Days enough
> To make a Week again."

MESSRS. BLACKIE AND SON have sent us the following works:—1. *Just Forty Winks.* By Hamish Hendry. Illustrated by Gertrude M. Bradley. Price 5*s.* This is what is generally called a fairy tale, although there are no fairies in it but plenty of talking beasts and other interesting creatures. We do not think that children will appreciate Mr. Hendry's disrespectful remarks about the House of Commons, but that will come later. They will, however, be delighted with the rest of the book and with Miss Bradley's charming illustrations, especially the one of the butterfly on the bicycle.—2. *Lords of the World: a Tale of the Fall of Carthage and Corinth.* By the Rev. Alfred Church. Illustrated by Ralph Peacock. Price 6*s.* Professor Church is well known as a successful writer and one who possesses the power of describing in a life-like manner events occurring in classical times. Schoolboys have been known to conceive a violent distaste for Roman history except, perhaps, as interpreted by the genius of Macaulay, but the boy who reads this book will certainly take an interest in the Punic wars. Professor Church has considerably reduced the horrors of the sacrifice to Moloch. It is a comfort to know that the wretched children were spared suffering but Flaubert's description of the same rite is infinitely more thrilling. Mr. Peacock's illustrations are good, but we fancy that any Roman officer would have recognised the girl in the frontispiece as a girl even in her man's dress.—3. *With Moore at Corunna.* By G. A. Henty. Illustrated by Wal. Paget. Price 6*s.* Mr. Henty is quite up to his best form in this book, and that is saying a great deal. His hero is like one of Lever's heroes and none the worse for that. It is just the book for a soldier's son, or indeed for any boy who likes a book full of adventures. Mr. Paget's drawings are very good.—4. *The Golden Galleon.* By Robert Leighton. With Illustrations by William Rainey. Price 5*s.* This is a narrative of the adventures of Master Gilbert Oglander and of how in the year 1591 he fought under the gallant Sir Richard Grenville in the great sea fight off Flores on board Her Majesty's ship *Revenge*. It is an interesting story of the conditions of life ashore and at sea in the days of Queen Elizabeth and the account of the famous battle between the *Revenge* and the Spanish ships (which Tennyson has so admirably portrayed in his well-known poem) is here excitingly recounted.—5. *With Crockett and Bowie; or, Fighting for the Lone Star Flag: a Tale of Texas.* By Kirk Munroe. With Illustrations by V. Perard. Price 5*s*.—The story of the struggle by which Texas threw off her allegiance to Mexico and retained her independence until of her own free will she threw in her lot with the great American Republic is the theme of this volume, and the account of the part played by Rex Harden and his beloved stallion Tawny in gaining for the Texans their freedom is admirably interwoven with the record of the historical struggle. The additional help of both Crockett and Bowie combine to make Kirk Munroe's book a storehouse of exciting adventures and an entertaining record of youthful pluck.

DIARIES.

Smith's Physicians' and Surgeons' Visiting List, Diary, Almanack, and Book of Engagements for 1898 (Hazell, Watson, and Viney, 59, Long-acre, W.C.) is now in its fifty-second year—a sufficient testimonial, if any were necessary, to the appreciation in which it is held by the profession. There is much useful information within its covers and it is conveniently shaped for the pocket. Not the least useful will be found the opening devoted to a record of "things lent" and to whom.

The Dental Surgeon's Daily Diary and Appointment Book. London: John Bale, Sons, and Danielsson, Ltd., 85-89, Great Titchfield-street, Oxford-street, W. Price 6*s.*—This diary for 1898 is, we are told, prepared under the advice and with the assistance and approval of many eminent members of the dental profession. It contains a large amount of information about dental hospitals, associations, and odontological societies in addition to that which is common to diaries in general. It has been specially got up and arranged for the object in view and will be found a very useful and convenient form of daily diary and appointment book.



THE RECENT EPIDEMIC OF TYPHOID FEVER AT CLIFTON.—At a meeting of the Bristol Health Committee held on Dec. 7th Dr. D. S. Davies reported that during the past six weeks the notifications of typhoid fever in Clifton for the weeks ending on the dates mentioned had been as follow: Oct. 30th, 100 cases; Nov. 6th, 60 cases; Nov. 13th, 19 cases; Nov. 20th, 9 cases; Nov. 27th, 2 cases; Dec. 4th, 2 cases. Dr. Davies stated that he anticipated that fresh cases would practically cease upon the expiry of a full incubation period of twenty-one days from Oct. 26th, when the contaminated milk was definitely stopped.

New Inventions.

LUPUS SCRAPERS.

ONE of the principal reasons why curetting operations for the relief of lupus are so frequently attended by unsatisfactory results is owing to the shape of the instruments with which they are performed. While Volckman's scoops are all that can be desired for the removal of nodules and small circumscribed areas, whether superficial or deep, they are quite unsuited for the removal of extensive patches of diseased tissue; therefore, Messrs. Mayer and Meltzer have made at

my suggestion a set of steel scrapers, three in number, the blades of which are slightly concave and measure ¼ in., ½ in., and 1 in. in length. They are beautifully finished out of one piece of steel, are fitted into a neat metal case, and in my hands have proved most useful, and, I trust, will prove a welcome addition to the armamentarium of the dermatologist.

G. G. STOPFORD TAYLOR, M.D. Durh.,
Honorary Physician, Liverpool Hospital for Cancer and Skin Diseases.

A COMBINED STAY-BELT.

IN many cases in which the muscles of the anterior abdominal wall are unduly lax, or in which a laparotomy has left a tendency to a ventral hernia, it is desirable to have some means of affording efficient support to the weakened structures. An objection to the ordinary abdominal belt is that it tends to rise up unless it is held in position by an understrap which is often far from comfortable. The Stay-belt has been designed to overcome this difficulty. It consists of an abdominal belt attached to the lower edge of a corset, and the requisite pressure is obtained by means of two steel bands, fastened at the back and in front bearing on the belt by means of a pad. We have examined a model of this stay-belt and we consider that in suitable cases it would form a comfortable and useful appliance, but it would need to be carefully fitted to the individual case. The makers are Messrs. K. R. Schramm and Co., of Great Castle-street, Oxford-circus, W.

METROPOLITAN HOSPITAL SUNDAY FUND.

THE annual general meeting of the constituents of the Metropolitan Hospital Sunday Fund was held in the Egyptian Hall of the Mansion House on Dec. 13th. The Right Honourable Horatio D. Davies, Lord Mayor, president and treasurer of the Fund, was in the chair, and amongst those present were the Bishop of Stepney, the Archdeacon of London, Canon Fleming, Sir Edmund H. Currie, Sir Stuart Knill, Lord Stamford, Dr. Glover, the Chief Rabbi (Rev. Dr. Adler), and Mr. Wakley. Letters regretting inability to attend had been received from the Dean of Westminster, Cardinal Vaughan, Rev. Dr. Rigg, Sir Dyce Duckworth, and others.

The LORD MAYOR, in moving the adoption of the report, said that the Hospital Sunday Fund was an institution which everyone must appreciate and it was most gratifying to see that it was steadily growing. This kind of charity appealed in an especial degree to the hearts of Englishmen and no effort would be wanting on his part to make it a great success.—The adoption of the report was seconded by the Rev. E. WARING, of St. Paul's, Bermondsey, and was agreed to.

Mr. F. H. NORMAN moved that some alterations should be made in Laws 2, 3, and 11, and that the following should be added to Law 5: "That where any hospital having an out-patient department has appointed a special and efficient officer for detecting any abuse in that department it shall be regarded by the Committee of Distribution as an important factor in determining 'Merits.'" He said that in consequence of persons eminent in the medical profession asserting that the out-patient departments had been grossly abused the Committee of Distribution had made an investigation and had come to the conclusion that although the charges had been very materially exaggerated yet there was reason to suppose that a certain amount of abuse existed. The Council accordingly sought to alter the laws so as to leave it to the Committee of Distribution to determine whether satisfactory measures had been taken to check such abuse. Law 5 provides that the awards shall have reference to the "merits" and "needs" of the institutions. The term "needs" denotes the amount of pecuniary assistance they require and "merits" takes account of whether they are skilfully and properly conducted. The result is that the appointment of an officer to prevent abuse in the out-patient department will entitle a hospital to more liberal treatment in the distribution.—Sir E. HAY CURRIE, in seconding the resolution, said that no harm and nothing but good could follow from having a properly trained man or woman in the hall to investigate the circumstances of patients. Sir Sydney Waterlow and his committee had been engaged in considering this question for a year past. The motion was agreed to.

The appointment of the Council for the year 1898 was moved by the Rev. C. H. GRUNDY, seconded by the Rev. Dr. HODSON, and agreed to.

The ARCHDEACON OF LONDON, in moving that June 12th be fixed for Hospital Sunday of 1898, said that last year's collection of £41,000 had been exceeded in seven different years, but only on one occasion very largely, when the amount was £60,000, great support having been given by members of the Stock Exchange.—The motion was seconded by Canon GRAHAM.—At this point the Rev. J. F. B. Tinling, of the City-road Congregational Church, commenced to protest against what he called "the increasing habit of vivisection" in hospitals, but was immediately ruled out of order by the Lord Mayor.—On a show of hands Archdeacon Sinclair's motion was agreed to with two dissentients, and the usual vote of thanks to the chairman, moved by the Chief Rabbi, terminated the proceedings.

HEALTH OF DEVONPORT.—Calculated on a population of 59 000 the death-rate at Devonport last year was 17·5 per 1000, the total number of deaths being 1033, the births for the same period numbered 1595, or 27 per 1000. The average number of deaths during the past ten years has been 1000 annually, or 16·9 per 1000, and the average births 1556 per annum, or 26 3 per 1000. In 1896 there were a higher birth-rate and a higher death-rate, the latter being caused by a greater prevalence of zymotic diseases.

SANITARY INSPECTORS' DINNER IN LIVERPOOL.—The tenth annual dinner in connexion with the North-western and Midland Sanitary Inspectors' Association was held on Saturday evening at the Compton Hotel, Liverpool, when there was a large attendance. The President (Mr. Francis Vacher, medical officer of health, Cheshire County Council) occupied the chair, and amongst those present were the Lord Mayor (Alderman J. Houlding), Councillor William Roberts, Dr. E. W. Hope (medical officer of health, Liverpool), Mr. Edward Sergeant (medical officer of health, Staffordshire County Council), Dr. William Carter, J.P. (Liverpool), Dr. E. P. Manby (assistant medical officer of health, Liverpool), Dr. S. G. Moore (Liverpool), Mr. Hewitt, J.P., C.A. (Cheshire County Council), and Dr. E. T. Whitaker (Shrewsbury); Professor Boyce (University College, Liverpool), Mr. T. E Sampson (Liverpool City Coroner), Mr. W. Hewitt, B.Sc., Mr. W. Urquhart (Crewe), Mr. H. H. Spears (honorary secretary), together with representatives from Manchester, Wigan, Barton, Bebington, Birkdale, Droylsden, Prescot, and St. Helens.

THE LANCET.

LONDON: SATURDAY, DECEMBER 18, 1897.

THE severe epidemics of typhoid fever which have lately afflicted Maidstone and Lynn will serve one good purpose. They will call, and indeed they have already called, general attention to the paramount importance of a pure water-supply and not only of a pure supply but of a supply the purity of which can be safely guarded and periodically tested. Already we find that sanitary authorities throughout the country are investigating the conditions under which their districts are supplied with water and are taking every means in their power to improve them. The state of things which exists in many towns and most rural districts is unsatisfactory, but the facts must be faced fairly.

A very large number of places are supplied with water by public companies, and it may be worth while to consider for a moment under what conditions these companies have come into existence, for the story of their origin counts for something in their inadequacy. A plentiful supply of water laid on to every house must be looked upon as a modern requirement; not many years ago it was considered a luxury and not a necessity. At that time sanitary authorities would not have had the support of the electors if they had undertaken any great public work to ensure an ample water-supply, so that the only way in which a supply could be afforded to a neighbourhood was by private enterprise. When the histories of many small water companies in towns and rural districts are carefully studied it is found that in very many instances the money necessary for carrying out the work of construction was provided at considerable risk by public-spirited individuals whose first wish was for the public good and who thought only secondarily of the profit likely to accrue to them. Many such companies worked for years against local opposition and only after a prolonged struggle were they successful in paying even a small dividend. The origin of other water companies will not bear so close an investigation. They have been started in a purely commercial spirit against which nothing is to be said, for in these matters no man need be public-spirited unless he likes. But the commercial spirit has in some cases, it is to be feared, led to actual wrong-doing. The local influence of petty officials in small towns has not always been fairly used and in their desire to spread the business with which they were connected they have wronged private individuals who possessed pure water-supplies of their own. These things must be mentioned because if on the one hand they are but considerations of minor and local importance their significance is always much insisted upon when there is any trouble between the local authorities and the water companies. The closing of a well will be quoted as an act of virtue when really it was an act of depredation, or the non-closing of a well may be a source of danger to the community whose safety has been allowed to rank second to the convenience of an important citizen. But, as we have said, these matters form side-issues. The main facts to be kept in the public mind are that pure drinking water is a matter of the first importance to the community and that the water-supply of every town and rural district should be sufficient in quantity for all domestic purposes and for flushing the drains—for we are not now considering any alternative method for the removal of sewage,—and its purity must be kept above suspicion by periodical examination. Elementary as this information must seem to our readers we assure them that it is imperative that they should keep it before their patients. There are many districts where such adequate and pure supply is not forthcoming. A medical officer of health is held responsible for the general sanitary condition of the district under his authority, which is equivalent to saying that he must use every means in his power to ensure to the district an adequate and pure water-supply. But water is supplied by private companies, and he has no power to examine or even to visit the property of these companies. Quite apart from any other local considerations which might hamper his work he may find himself unable to visit the waterworks of his district.

This question has lately been prominently brought into notice by the Sanitary Committee of the town of Stockport. Dr. PORTER, the medical officer of health for the borough, has called the attention of the Council to the conditions which exist at the gathering ground used for the collection of some of the water being supplied to the town. Dr. PORTER was unable to visit the whole of the catchment area, but from the report which he gave of the part which he did visit it would appear that the state of things existing there was most unsatisfactory. Into the unsavoury details we need not at present enter. In his report Dr. PORTER called the attention of the Sanitary Committee to the fact that as he was held responsible for the sanitary condition of the town it was an anomalous state of things that the law did not allow him the same power of supervision over the water-supply which is given in the case of foods and drinks. Acting on this report the Stockport Town Council after considerable discussion passed a resolution to the following effect:—

"That inasmuch as outside the metropolis and except in regard to wells and pumps sanitary authorities possess no executive powers for the protection of public water-supplies in the hands of water companies, whereas the consumers of flesh, milk, and other foods are safeguarded by statute, this committee respectfully recommends that a petition be presented to the Local Government Board, under the seal of the Council, praying that legislation be initiated whereby every sanitary authority supplied by a water company which is not also a sanitary authority be empowered to authorise any duly appointed official to enter, inspect, inquire, and take samples at any part of any source or works of water-supply or water purification, at any time by day or night, and whereby also such water company be required to afford all reasonable facilities and information for such inspection, inquiry, and sampling."

The resolution of the Stockport Sanitary Committee is one of considerable importance and may, and we hope will, lead to good results. The matter of the control of the water-supplies is one of great difficulty and complexity, but there is no doubt that if the medical officer of health for any district were legally entitled to examine the way in which water was

Digitized by Google

collected and purified and if he had power of entry not as a matter of courtesy but as a matter of right to all parts of the water companies' premises he would be in a much better position than he is at present to protect the interests of those for whose health he is held responsible. With regard to the immediate practical outcome of the resolution we may, however, point out that legislation on matters of sanitary import is not initiated by the Local Government Board's medical officers. The discussion and resolution initiated by the Stockport Town Council need not on that account necessarily be without effect. The interest excited at so important a town on the question of their water-supply and the fact that the public authorities are taking all the means in their power to improve it without waiting for the exciting cause of a prevalent epidemic make most satisfactory hearing, and we are pleased to see that a member of the Corporation in the course of his speech quoted at length some weighty words of the late Sir GEORGE BUCHANAN to the effect that in obtaining a pure water-supply it was unnecessary to rely on chemists who "can in brief tell us of impurity and hazard but not of purity and safety." With the advantage of an active medical officer of health and an enlightened council the Corporation of Stockport should be able to bring popular pressure so strongly to bear on the water company which supplies them that the gross impurities which at present are alleged to corrupt the catchment area of their water-supply may be at once removed and never allowed to recur. In the case of local water supplies the initiative must always come from the place affected. More is to be hoped for from well-informed local popular opinion than from the supervision of a central authority. When the people of any town or district are thoroughly resolved to improve the sanitary conditions under which they live the matter can always be done. In the past the chief troubles of the medical officers of the Local Government Board have been caused by the opposition of sanitary authorities to any suggested improvements. The most satisfactory indications for the future with regard to the public health of the people of this country are to be found in the increased and increasing interest which is manifested by sanitary authorities in the improvement of the hygienic conditions of the people, and in the spread of knowledge of the causes and of the means of prevention of epidemic disease.

CONCERNED as it is with all matters affecting the health of the community our profession cannot view with indifference the question of the training of weak-minded children, of whom such large and increasing numbers are to be found among the lower classes. The institution known for the sake of brevity by the somewhat inappropriate name of the Darenth Schools, but the full style of which is the Darenth Asylum and Schools, has lately occupied a good deal of the attention of the Metropolitan Asylums Board, and it is with a sense of relief that we record the fact because it is high time for reformation in this quarter. In reality this large establishment consists of two hitherto separate institutions within the same curtilage—viz., the Darenth Imbecile Asylum and the Darenth Idiot Schools, each containing approximately 1000 inmates, and each under a separate medical superintendent. But at a recent meeting of the Metropolitan Asylums Board a report of the General Purposes Committee was brought up recommending that both institutions should be placed under one medical superintendent. This was followed by a series of contingent proposals which have for their object the utilisation of the Brighton-road Schools at Sutton for the reception of "helpless or industrial imbeciles," such as are now received at Darenth; and the conversion of the two separate establishments at Darenth into one huge school "devoted exclusively to the reception of children capable of receiving some degree of instruction."

Here, then, are two gigantic institutions, which are already too large for anything like personal supervision to be exercised over the inmates—and in which some members of the Board, in the discussion which followed, alleged that deficient and faulty classification already exists—which are to be amalgamated, and this in spite of recent revelations concerning the evils of huge institutions for the training of the young. It is idle to urge that a large number of the inmates are of the imbecile and incurable class and that in the event of "the Brighton-road Schools at Sutton becoming available, they should be used to relieve the pressure at Darenth." The facts remain that by the proposals of the managers, if they are correctly reported, there will be for a considerable time a population of over 1500 inmates consisting of a major proportion of trainable, as well as incurable, weak-minded persons, herded together without adequate classification. Even when "the pressure has been relieved" and a normal standard has been attained there will still exist an institution for the training of weak-minded children which in point of size will rival or exceed many of those condemned by the Departmental Committee. The sum of £377,000 is stated to have been expended on the Darenth Asylum and Schools, and almost the only argument advanced—at any rate the only one which can be seriously and reasonably urged—in support of these proposals is economy—viz., the utilisation of this collection of buildings already in existence. But surely this is false economy when the facts are closely examined in the light of modern views on educational matters.

If these large schools are bad for the education of normal children—and this was proved beyond doubt by the Departmental Committee—how much worse are they for abnormal, weak-minded children who differ from each other in an infinite number of ways. Many of these latter by careful personal supervision are capable of becoming very useful and wage-earning members of the community; but if dealt with "in bulk," in a mechanical manner, they almost invariably drift into a life of useless imbecility. Moreover, if they are associated by faulty classification with children of a lower grade of intelligence they themselves are degraded in intellect and the hopeful cases become quite hopeless. Dr. DOWNES, the Local Government Board inspector, is reported to have said at the meeting of the Metropolitan Asylums Board above alluded to that "he should have the greatest hesitation in assenting to a scheme which would leave the comparatively educable children part and parcel of one enormous institution"; and we sincerely trust that the Central Board will take the same view of this

Digitized by Google

ill-advised proposal, and decline to sanction the perpetuation, nay rather, the accentuation—for the intention is to amalgamate two institutions which are already too large—of this mistaken policy.

THE question of hospital abuse has been to the fore for some time past, but recently an incident has occurred at Newport, Monmouth, which bids fair, to use a legal expression, to become a ruling case. The facts are as follows. The honorary ophthalmic surgeon to the Newport Infirmary is Mr. H. C. ENSOR and a short time ago two patients went to the infirmary to consult him, their position, in his opinion, not being such as to warrant their seeking charitable relief. Accordingly he refused to treat them, the board of directors took up the matter and applied to Mr. ENSOR, who gave his reasons for the refusal. The board then wrote to one of the would-be patients asking her to come up again, which she did, and again Mr. ENSOR refused to treat her. Accordingly the board of directors intimated to Mr. ENSOR that "his valuable services" as ophthalmic surgeon would be dispensed with at the end of the year. The facts concerning one case are as follows. The family, by the patient's own statement, earn £117 per annum and in addition the mother keeps a small shop. In the other case the father earns 35*s.* a week and the proposed patient 24*s.* a week. The medical staff of the infirmary held a meeting on Friday, Dec. 10th, but the result of their deliberations have not been made public. The Cardiff Medical Society, at a meeting held on the same day, unanimously passed a resolution as follows:—

"The members of the Cardiff Medical Society having heard Mr. ENSOR'S statement and having duly considered the statement of the Chairman of Directors of the Newport Infirmary, which appeared in the public press, unanimously express their sympathy with Mr. ENSOR in the position in which he has been placed and their sincere hope that the Board may see their way to withdrawing their notice."

The statement of Mr. Alderman DAVIS, the Chairman of Directors, as given in the *Western Mail* of Dec. 11th, was to the effect that Mr. ENSOR had been told that the directors would look at the end of the year for another ophthalmic surgeon, that it was not the first time that Mr. ENSOR had declined to treat cases which the directors upon inquiry had found to be in their opinion suitable persons to receive gratuitous treatment, and that the directors must be the judges. A man might be respectably dressed and be earning 30*s.* a week, but that was not sufficient guide unless all his circumstances were inquired into and a fee of a guinea for treatment was a good deal for poor people.

Such, then, are the facts of the case as it now stands and technically it must be allowed that Mr. ENSOR, as he himself confesses, is in the wrong, for he accepted the post well-knowing that he would be in a subordinate position to the directors. But from another point of view it is surely the obvious duty of an officer of a charity to do his utmost to prevent abuse of that charity and it is owing to action of this kind that Mr. ENSOR has come into conflict with the directors, and we consider that he is much to be commended in that he as a consultant has not feared to face obloquy by his stand for the good of both the hospitals and the profession at large. It is perfectly true, as the directors argue, that weekly income is no sure guide to whether a man is or is not a fit recipient of charity; many a poor cleric or struggling member of the other professions may be earning £4 a week and yet owing to the circumstances of his position be much worse off than another whose income is only 30*s.* or £2 a week. But surely the two cases which have brought the matter to a head do not come under the category of being eligible objects for charity; either of the patients in question could certainly afford a five-shilling fee and *pace* Mr. Alderman DAVIS there must be plenty of capable practitioners in Newport or Cardiff who would see patients for less than a guinea.

Difficulties such as the above always arise and probably always will arise at hospitals where the income is dependent upon the subscriptions of the charitable, for human nature being what it is, the average subscriber looks for a return for his charity not only in the world to come but in this as well, and therefore he demands and procures letters of recommendation which are in the majority of cases distributed without any inquiry as to the fitness of the recipient. Hence comes the appearance of the well-to-do patient at the hospital, the refusal of the conscientious medical officer to abuse the charity, the appeal to the governing body, and the old argument, "If we refuse the patient we shall offend the subscriber who gave the letter; if we offend the subscribers the funds of the charity will suffer." Such we expect has been the course of events at Newport, but we may hope that matters may yet be settled amicably. Mr. ENSOR is anxious for some arrangement to be arrived at and we are sure the directors are so too. The governing body of the infirmary has for its president Lord TREDEGAR, who is also a vice-president of the Hospital Reform Association, a fact which of itself makes for peace, and four of the medical officers to the charity are *ex officio* members of the board of management. There will have to be something given up on the part of both sides, for no doubt there is something to be said for the point of view of either, but disputes about the management of a charity are bad in every way. The prestige of the institution is lowered, its usefulness as a helper of the poor and needy is impaired, and the cause of charity generally throughout the kingdom may be injured, by a scandal arising at any one institution for dispensing relief. For all these reasons we would counsel that if possible some agreement be arrived at.

The position of the directors is apparently that after a patient has been refused advice inquiry is made and occasionally it is found that the said patient is a worthy object for relief. Would it not be better in every way that inquiry should be made before the letter of recommendation is given or if this is too Utopian a scheme that inquiry should be made by some other than the medica officer when the patient presents his letter at the hospital? The problem of hospital relief and abuse of the same is no doubt a very hard one to solve, but the hoped-for solution will never be found unless the representatives, if we may call them so, of both sides of the question, those who look at it from the point of view of the medical man and those who approach it as subscribers, will unite in working together for the common good.

"Ne quid nimis."

THE LANCET SPECIAL COMMISSION ON THE METROPOLITAN WATER-SUPPLY.

WITH the article which appears in our columns on page 1610 this important Commission comes to a close. Its scope was limited, but its work was designed to be exhaustive within those limits. We did not desire to write of the water-supply of London from the point of view of its adequacy or purity or to make the subject an opportunity of introducing into our columns discussions upon municipal or Imperial politics. Our object was to give our readers information by which they would be enabled to form sound judgment as to any proposals that in the future — and possibly in the near future—might be made for the reform of the metropolitan water-supply. Before any reform can have logical reasons it is necessary that the present condition of the thing to be reformed should be thoroughly known. That is the information which our Commissioner has been content to give. That it has already proved of great value to many persons we have been glad to learn from letters that we have received; that it has been opportune is shown by the character of the evidence now being taken before the Royal Commission presided over by Lord Llandaff. Our Commissioner has described the present condition of the metropolitan waterworks and to the comprehension of any scheme in the future this knowledge is indispensable.

A CENTRAL HOSPITAL BOARD FOR LONDON.

ON Monday last the first report of the General Committee for the Promotion of a Hospital Board for London was read and discussed at a meeting of the Charity Organisation Society. To this meeting the chairmen and treasurers of the different metropolitan hospitals as well as members of the medical profession were cordially invited and those who attended were rewarded by interesting proceedings. These proceedings will be found reported elsewhere. The profession was in good evidence and was represented among others by Sir Wm. Broadbent, Sir Joseph Fayrer, Dr. Glover, and Mr. Victor Horsley, but the chairmen and treasurers of hospitals were notably absent or at least notably silent. In this abstention of the officials from debate lies the chief difficulty of the situation—at least, so it seems to the promotors of the reforming scheme. The authorities of individual hospitals are reluctant to recognise the need of a central body. They appear not to see that such a board would facilitate their work by enabling them to face with united front the abuse of charity from which they are suffering. It is to be hoped that this reluctance will be overcome. The demand for more system and principle in the administration of hospital charity does not come primarily from the profession but from the public. The need for reform in the administration of hospitals is not the greedy cry of a class directed against the managers of hospitals. The language of Sir William Broadbent and Sir Joseph Fayrer on this point is conclusive as regards the medical profession. It is really the public who are showing their sense of hospital management in an unmistakeable way. With the existing number of wealthy people it is impossible to interpret the impecunious plight of our deserving hospitals on any other theory than that of distrust of their administration. A grave responsibility now rests on the governing bodies of hospitals and they must accept the principle of some common board to which they can look for an impartial judgment of their work and of its claims on the public. They have indeed done so by the formation of the Central Hospital Association. They will do well to show some activity in the use of this association and even to extend the conception of it till it shall include all respectable hospitals and representatives of all who wish them well. The governing bodies of such dispensaries as are conscious of a good *raison d'être* would do well to follow the example of the general hospitals and adapt their institutions to the altered circumstances of the day. They may be needed to take over some of the work which the hospitals may find it right to refuse. By such action and by a little mutual coöperation hospitals and dispensaries might have a new lease of public confidence and of prosperity and might even forestall the action of those who seek to create a central hospital board. But united action must not be long delayed, while the approaching distribution of the Prince of Wales's Fund makes of the present an auspicious time. Resistance to public opinion displayed in such unequivocal fashion can only tend to injure institutions of which we are all proud. The governing bodies of our medical charities should rise to the occasion and meet the public demand for their more efficient and harmonious coöperation and should rise at once.

"MODIFIED MILK" FOR INFANT FEEDING.

A NEW departure in the feeding of infants has been described in a recent paper by Dr. D. J. Evans, of Montreal Foundling Hospital. The essence of the new method consists in the substitution of a "modified" cow's milk for the natural product. The writer maintains that an ideal milk for infants must preserve a certain regulated proportion between the proteid, fatty, and saccharine constituents, that this proportion should vary with the age and the digestive system of the child, and that excess not only of the whole but of one or other of its constituents is accountable for the gastro-intestinal troubles of infancy. Thus an excess of the proteid elements gives rise to vomiting, constipation, less commonly diarrhœa, colic, and the passage of small, hard curds. He considers that "as a rule proper management of proteids means success in infant feeding." Excess of fat causes frequent evacuation with soft curds and vomiting but seldom colic. Excess of sugar leads to colic and thin yeasty motions. He finds the "modified milk" most useful for premature, feeble, and marasmic infants and in the treatment of summer diarrhœa. This milk is prepared by adding solutions containing definite percentages of cream or sugar to milk so as to obtain the desired proportions of each of the components needful for nutrition. This process can be carried out at home by a careful nurse or, if preferred, with greater ease in the laboratory. The milk should also be sterilised. Some of the details given in this paper are to our mind too strongly suggestive of an effort to improve upon nature or even to do away with the services of that "homely nurse" altogether. We quote an example. A table gives the following average composition of human milk: fat, 4·00; sugar, 7·00; proteid, 1·50. In a subsequent passage the writer says: "An average formula for a healthy infant during the first week of life would be: fat, 2·00; sugar, 6·00; proteid, 0·60. The percentage may ..... reach: fat, 3·00; sugar, 6·00; proteid, 1·00 by the end of the first month." Not till the third month does he allow milk of the average composition. In prescribing the amount of milk he is even more sparing, from 10 to 16 ounces per diem at the end of the first week being increased to from 30 to 40 ounces from the *sixth to the ninth month*. Excellent results are claimed for this method of artificial nourishment which we are informed sustains at the present time 30,000 infants in Canada and the United States. Dr. Rotch, of Boston, U.S., who is the originator, states that of 115

Digitized by Google

children suffering from diarrhœa and thus fed 109 recovered. Such reports are certainly very encouraging. We feel sure that they will obtain for the new mode of feeding full justice in its trial. We confess, however, that we cannot agree with the writer of this paper in what appears to us to be his wholesale distrust of the provision made by nature for the needs of infancy. We cannot but think that his process errs by over-elaboration of those simpler measures by which with some judicious help in times of difficulty she has on the whole very successfully reared the race of man through countless generations.

THE SANITARY CONDITION OF THE FRENCH ARMY IN 1895.

THE Medical Department of the French War Office has just published some medical statistics of the army during the year 1895, and from their very interesting report we take the facts and figures which follow. The total number of admissions to infirmary and hospital is given as 313,579, answering to a general sickness-rate of 631 per 1000 efficients. This proportion is much higher than that of preceding years. There were 3933 deaths during the year, of which 197 in hospital occurred in men belonging to the Madagascar expeditionary force. Of 1000 deaths typhoid fever caused a mortality of less than a quarter instead of a quarter or even a third, as was the case in former years. Next came tuberculosis, influenza, pneumonia, and bronchitis. The year 1895 was marked by a great recrudescence of influenza, the disease being of a very grave type and attended by a greater mortality than had hitherto been known in the army under this head. 22,407 men were admitted to hospital for influenza; about 90,000 were treated without admission and 484 deaths were attributed directly to this disease. As to mortality the 1st corps was, as usual, the one which suffered least. It was closely followed by the 2nd, which also as a rule is a particularly healthy body. Then came the 16th, 15th, 3rd, 6th, 11th, 18th, 12th, 4th, and 10th corps; the Paris garrison, the 8th, 14th, 7th, 19th, 9th, and 13th corps; the divisions of Algiers, Constantine, Tunis, and Oran, this last being specially affected by typhoid fever. The classification according to branch of service, beginning with those which suffered least, gives the following order: fire brigade, the writers of the staff and recruiting department, clerks and employés of the War Office, *ouvriers d'artillerie*, artificers, engineer regiments (*la génie*), republican guard, *chasseurs à pied*, the cavalry, the garrison artillery, and the infantry of the line. The list ends with the prison and penitentiary officials, the army of Africa, the foreign legion, the pioneers, and the military police. To sum up, the branches of the service which come off best are those in France which are made up of a small body of men or are scattered over a large area, and those which suffered most represent the unfavourable elements of the army of Algeria. There were 52 cases of sudden death, 221 accidental deaths, and 135 suicides, of which half were by gunshot wounds, one-third by hanging, and the remainder by drowning or jumping from a height. Of the 410,044 reserve men called out in 1895 there were 8575 treated in the infirmary, 2041 in the hospital, and 33,474 treated without admission, 3825 were discharged for various reasons, and 80 died during their period of training. The medical report in conclusion draws special attention to the insanitary state of the barrack of Babylon in Paris, shut in between two narrow streets and surrounding houses. In 1895 there were in this barrack 330 sick and 12 deaths in one battalion of the 130th regiment of infantry, while the second battalion of the same regiment, quartered at the École Militaire had only a fourth of the number of sick and no deaths. But for the influenza epidemic the garrison of Paris was in a very healthy condition during 1895. The number of soldiers pensioned off or discharged for sickness or wounds was 15,145, of whom 77 were officers placed on the retired list, 367 were cases of sick leave under Class 1, comprising 331 who were allowed a bonus, and 14,569 were cases of sick leave under Class 2. This large increase in the number of discharges is due to the weeding out from the ranks of a large number of young men who in 1894 had been enrolled as "bons avec infirmités." At their meeting of April 8th last the Conseil Général adopted a proposition with a view to diminishing the number of soldiers attacked by tuberculosis. The first part of this proposal is as follows: "The Conseil Général, struck by the constantly increasing ravages of tuberculosis among young soldiers, recommends that the medical examination of young soldiers should be very much more strict and that after a careful examination men already attacked by, or suspected of, tuberculosis should be rigorously excluded." M. Dubois remarked at the meeting of Nov. 24th that even the most skilful military medical man could not examine and decide in a few seconds as to the health of the young soldier who came before him. It would be desirable for the information of the military surgeon that certificates granted by the ordinary medical attendant of the recruit should be taken into consideration. As an outcome of this the Conseil Général unanimously passed the following: "That the military authorities may legally accept the reports and certificates of civilian medical officers who have attended the young men who present themselves for medical examination to serve in the army; that every young man suspected of tuberculosis should be kept under observation of a very thorough character; and that he should not be attached to a regiment unless bacteriological examination showed the absence of Koch's bacillus."

BERI-BERI AT THE RICHMOND DISTRICT ASYLUM, DUBLIN.

THIS asylum serves the counties of Dublin, Louth, and Wicklow together with the City of Dublin and the town of Drogheda with an estimated population of 552,390. The legal limits of accommodation allow for 1100—viz., 505 males and 595 females—but the "legal accommodation of the original buildings is an over estimate as they are incapable of affording proper accommodation for more than 1000 patients." The total number of patients on the books on Dec. 31st, 1896, was as follows:—males, 861; females, 867; total, 1728. Of these 59 male patients resided in the old residence at Portrane, 39 female patients were housed by night in the former quarters of the medical superintendent, and provision was made for 264 patients in the temporary buildings erected by the Board of Governors at the Richmond Asylum. It is obvious, however, that the building is much overcrowded and it reflects the greatest credit upon the management, both medical and otherwise, that the death-rate should only have been 7·8 per cent. for the year 1896. Of the total deaths 30·5 were due to phthisis. The most important disease, however, which visited the asylum was undoubtedly an epidemic of beri-beri. There were 8 deaths from this cause—2 males and 6 females. The attacks among patients numbered 109—32 males and 77 females, while 7 nurses were attacked in addition. Nothing seems to be known as to the origin of the disease, which first appeared in 1894, but according to the report of Dr. Patrick Manson "a germ of foreign origin was fostered by the excessive overcrowding, defective ventilation, and dampness which was patent at the time of my visit both in many of the day rooms, in the dormitories, and even in the hospital wards of the Richmond Asylum." Dr. Manson goes on to say that the only method of getting rid of the disease is prompt and thorough relief of overcrowding together with a number

Digitized by Google

of sanitary and hygienic improvements. Dr. Walter Smith and Sir Thornley Stoker say practically the same thing. The inspection by these gentlemen was made on Oct. 16th, 1896. There would seem, therefore, to be a very strong opinion with regard to the necessity of getting rid in some manner or other of the overcrowding and the authorities are doing their utmost to bring this about. The question of boarding patients out was discussed, but owing to legal difficulties did not come to anything. A new asylum is in course of erection at Portrane which will provide sleeping accommodation for 665 men and 733 women besides 128 attendants and at present there is temporary accommodation for 100 men at Portrane.

DOMESTIC HYGIENE.

As a general rule lectures on medical subjects delivered at a lay public are much to be deprecated. They are likely to produce an entirely wrong impression on the members of the audience when previous education and want of knowledge of physiology and the kindred branches of science do not prepare them for a right mental assimilation of the facts laid before them. There is one branch of medical knowledge, however, in respect to which exception must be allowed in giving expression to the above opinion and that is as regards matters concerning domestic hygiene. The utmost ignorance is generally displayed on this subject, by the poorer classes especially, and consequently the announcement made by the Mansion House Council on the Dwellings of the Poor that arrangements are being concluded for the delivery in the various districts of London of lectures on "Healthy Homes," and "Essentials of House Sanitation" is to be commended. The question remains whether the desired audiences will be obtained. Not only ignorance but utter want of interest are exhibited on such matters by the classes referred to, but we wish the council every success in their endeavours to instil into the minds of the people the most simple and essential points concerning the hygiene of home and body.

POST-MORTEM DELIVERY.

IN German medical literature is found a term for which as far as we are aware there is no English equivalent, viz., "Sarggeburt," which literally translated means "coffin-birth"—that is to say, that a pregnant woman dies and the body is placed in a coffin and then before or after burial delivery takes place. Very few cases of this kind are on record. A notable case, however, is recorded by Dr. Bleich, of Tschirnau.[1] Before proceeding to describe the case Dr. Bleich makes some remarks on the theories that have been advanced to account for the causes which bring about post-mortem delivery and states that two explanations have been advanced; the first supposes that the pressure produced in the abdomen by the gases evolved in post-mortem decomposition is sufficient to cause the expulsion of the uterine contents, whilst the second suggests that the necessary force is brought about by the condition of rigor mortis into which the muscular structure of the womb is thrown. Proceeding then to a description of the case which he himself observed, Dr. Bleich records that on July 6th the dead body of a woman was found lying in a shallow pool of water. It was ascertained that she had escaped from her home in a state of insanity. On examination no signs of injury could be found with the exception of slight bruises on the knees; it was found that she was pregnant, probably in about the seventh month. Post-mortem rigidity was present; a few post-mortem stains were found on the back. It was concluded that the body had only been a short time in the water and that all the evidence pointed to suicide, and the burial took place on July 9th. Eight days after the finding of the body it was ascertained that three young labourers had had sexual intercourse with the deceased woman shortly after one another. They were arrested and closely questioned and all three persistently denied that any criminal force had been used, but, on the contrary, said that the woman had been a consenting party. Exhumation of the body was ordered and a post-mortem examination was made on July 19th. Delivery was found to have taken place after the coffin had been closed with complete inversion and prolapse of the uterus and vagina. A full account of the necropsy is given in Dr. Bleich's paper. We can only give a brief abstract. The abdomen was greatly distended but exhibited no signs of injury. Between the thighs lay a dark-red mass (the uterus) about the size of a head, from the under side of which sprang a dark umbilical cord, and connected with the latter was the body of a child 36 cm. in length. The vulva was wide open. The uterus was flabby and like a sac and lay with its inner surface pressed against the thighs together with the vagina; the placenta had separated and was dark-brown in colour and of a hard consistence. The muscular walls were thin and brittle. Dr. Bleich suggests that the violence experienced by the woman shortly before death had been of such a nature as to render abortion probable and that the collection of the gases of decomposition in the abdomen had been sufficient to complete that process and also cause the condition of the uterus found on the exhumation of the body.

OVERCROWDING IN LONDON.

THE London County Council on Tuesday took a step which will have an influence on the health and welfare of the London inhabitants more important perhaps than any action taken by that body since it was called into existence in 1889. One of the most difficult tasks which has to be undertaken is that of dealing with overcrowding in the metropolis. The erection of artisans' dwellings is a step in the right direction, but this can be met by the enterprise of public companies and by the natural tendency of private builders to provide accommodation whenever the need for this provision is such as to ensure that the accommodation will be utilised. The great difficulty is to prevent overcrowding and all the evils which are attendant on overcrowding in dwellings which already exist. The only means which the Council possesses of dealing with this question is to ensure that by the regulation of houses let in lodgings of the poorer sort there shall be no overcrowding within them. A report just issued by the Public Health Department of the County Council shows that the majority of the sanitary authorities have been very lax in exercising the power with which the wisdom of Mr. Ritchie provided them in 1891. The Council, after waiting until the sanitary authorities had made by-laws and until a sufficient time had elapsed for them to undertake the work, has caused inquiry to be made into the progress they have accomplished, with the result that it has been found necessary to make complaint to the Local Government Board of one authority which has made default in enforcing this provision of the Act. The authority which has been selected by the Public Health Committee for this purpose is the vestry of Bethnal-green, but the discussion in the Council showed that other authorities have been equally lax in the administration of the law. The question arose whether these other authorities should be dealt with in a similar manner, and Dr. Forman, the chairman of the Public Health Committee, at once on behalf of his committee expressed willingness to make complaint of all defaulters. The Council evidently hoped that it would prove sufficient to make an example of one authority, but the position assumed by Dr. Forman and the support he received

Digitized by Google

from both parties in the Council showed plainly enough that the recommendation of his committee was merely a beginning and that his committee and the Council had fully made up their minds that every effort should be made to raise the standard of house accommodation for the poor throughout London. The vestry of Bethnal Green will therefore be complained of and in the meantime it may be expected that other sanitary authorities will carefully consider how far they have done their duty. We are sure the lesson to be learned from Tuesday's proceedings will not be thrown away and that London will now seriously address itself to this important work. Whatever changes may be made in the Council as the result of the next election there will evidently be no hesitation in persevering with the work which had its beginning this week.

HOSPITAL ACCOMMODATION FOR SMALL-POX.

THE Local Government Board inquiry which was held at the Town Hall, Croydon, on Dec. 9th is of considerable interest in reference to the very difficult question of the proper isolation of small-pox. We use the term "proper" isolation since it is obvious that the treatment of small-pox in hospitals surrounded by inhabited houses can in no sense be considered as such; indeed it is, as has been found over and over again, one of the readiest means of spreading the disease. At the inquiry to which we refer it was proposed that the Local Government Board should issue a Provisional Order under Section 279 of the Public Health Act, 1875, forming the County Borough of Croydon, the Urban District of Wimbledon, and the Rural District of Croydon into a United District for the purpose of providing hospital accommodation for the reception of cases of small-pox; and as there was no opposition to this proposal we infer that the provisional order will be issued, with such modifications as were discussed at the meeting, and that the joint board will be formed. This solution of the hospital difficulty seems to us the best that can be devised under all the circumstances, and fortunately there is no serious contra-indication to the conveyance from long distances of patients suffering from this disease. Moreover, there is no reason why a joint board such as that now in question should not erect several small-pox hospitals should the occasion demand. When the question of site or sites comes to be considered there will doubtless be some outcry from the neighbourhood selected, but this is inevitable and in the joint district there should be found comparatively uninhabited areas in which the small-pox hospital or hospitals might safely be erected.

EPIDURAL ABSCESS WITH ABSCESS IN THE BRAIN.

IN the November number of the *American Journal of the Medical Sciences* Dr. Charles H. Burnett gives an account of an interesting and very important case. A man, aged thirty years, who was said to have had a discharge from his left ear ever since childhood, was admitted to hospital in a semi-comatose condition. He seemed to understand questions but was unable to answer them and he could not protrude his tongue, simply opening his mouth when asked to do so. His appetite was fair, his digestion good, and his bowels were not constipated. The history was that ten days before admission he complained of earache and toothache on the left side and he had a tooth drawn. The pain continued and three days later he came home from his work complaining of pain in the left ear, headache, and nausea, and he actually vomited. Three days before admission he was able to sit up in bed, but in the afternoon he became suddenly unconscious and in the course of the evening had two severe convulsions. After this he remained semi-comatose and paraphasic, the condition in which he was on admission to hospital. He was found to have a granulation in the left ear which was removed. It was then seen that the tympanic membrane had disappeared, the promontory was red and sensitive, there was a flabby granulation protruding from the antrum into the auditory canal, and a large perforation into the attic. It was decided to explore by way of the mastoid. No pus was found, only crumbling bone and two or three granulations which were removed from the antrum. The temporal bone was then trephined, the lower edge of the trephine hole being situated about an inch above the external auditory meatus. A director was passed between the dura mater and the bone and about two drachms of offensive pus escaped. In spite of this operation the aphasia increased, the patient became quite incoherent, and there was great restlessness at night affecting chiefly the right arm and leg. A communication was next established between the epidural abscess cavity and the drum cavity, but without affording any relief. It was then thought that there must be a collection of pus in the brain, most probably in the temporal lobe, and it was decided to explore. About half an ounce of thick, greenish, offensive pus escaped and a drain was inserted by which pus continued to discharge. The patient, however, did not recover consciousness and died comatose with a high temperature two days later. A necropsy unfortunately was not permitted. Dr. Burnett remarks that the conditions in this case indicated a pyæmic condition rather than a simple cerebral abscess. Considerable variation in the temperature took place and it would naturally be expected that thrombosis had occurred in the sinuses, although the variations of temperature were the only indication of such a condition. It is unfortunate that inspection of the actual condition present in the brain was not permitted.

NILE BARRAGES.

THE International Controllers of the Egyptian *Caisse* have, according to Reuter, relaxed their purse-strings to the extent of over half a million sterling for the purpose of repairing existing barrages in the Nile and creating new ones, and they are also said to have conceded £100,000 for renewal of railway material. These large concessions are apparently in addition to a grant of £150,000 which was recently accorded to the irrigation department, in which case the total sum released from the swollen reserve fund would amount to no less than £780,000. It seems that the great barrage below Cairo which was originally constructed by French engineers has again been injured by under-springs and that its "holding-up" power has consequently been considerably diminished. This of course is by no means surprising for the enormous structure stands upon alluvium and is yearly subjected to immense pressure while the river is in flood. Under the circumstances the wonder is that it has not long since been swept away. We also learn from the same source that great satisfaction is expressed at the action of the members of the *Caisse* in thus facilitating works which are considered most necessary for the public welfare. Doubtless from a purely fiscal point of view damming the Nile may be expedient, but that interference with the current in Lower Egypt should conduce to the public welfare is open to question. We have frequently alluded to the bad quality for drinking purposes of stagnant Nile water and some months ago we published tables showing an appalling death-rate among young children throughout the low-Nile season.[1] The schemes for impounding the Nile in its comparatively pure and uncontaminated upper reaches, about which so much used to be heard, are now no longer mentioned. Together

[1] THE LANCET, April 10th, 1897, p. 1040.

Digitized by Google

with the scheme for the drainage of Cairo they seem to have been relegated to the limbo reserved for Utopian projects. To the humanitarian this abandonment of the Upper Egypt reservoirs is discouraging and depressing. The Nile is the sole source of drinking-water in the country, and until the great river can be effectually purified during the summer we cannot hope to see any sensible diminution of infantile mortality.

"TEMPORA MUTANTUR, NOS ET MUTAMUR IN ILLIS."

A LETTER with this familiar quotation as a title appeared in our columns on Dec. 11th, signed "Paterfamilias." It told a sad story in simple language and as a result a well-known surgeon has made a generous offer to the writer. "Paterfamilias," a general practitioner, after enumerating the causes that with no blame to himself had thrown him "into a position of great difficulty and distress," went on to say: "My youngest son, who is commencing his third winter [of medical study] has received notice that unless his fees, amounting to £30, are paid forthwith he will be excluded from lectures. He is an ardent and eager student and it will be heart-breaking work if I have to keep him at home, but I do not know how to get the money. I have already paid £80 to the hospital besides examination fees. What can I do?" The offer of "Paterfamilias's" unknown friend made hereby through our columns is as follows: "I presume you [i.e., THE LANCET] guarantee the facts by your insertion of the letter. If this be so I will give £5 towards paying the boy's fees if five other men will give an equal amount or the £25 in other ways be made up in time." To this we have to say that we have "Paterfamilias's" full permission to apply for information at the hospital, and that he has referred us to the senior surgeon of the hospital and to the dean for confirmation of his story. We hope under these circumstances that some of our readers will place us in the position of being able to send "Paterfamilias" a cheque for the lad's fees. A little help now may be the means of securing to him a career and a professional position for life. The time is opportune for the extension of a kindly hand towards such a case. Not so long ago a student in this position, keen at his work and the son of a medical man, could have sold his services by taking an unqualified assistancy and could thus have tided over the evil spell, but this resource is now impossible. Moreover, Christmas is upon us—the season when generosity should not stand much on the order of its giving but should give at once.

TRANSPLANTATION OF MUSCLES IN THE TREATMENT OF DEFORMITIES.

THE ingenious method of remedying loss of power and deformity from paralysis of certain muscles by attaching their tendons to those of others is of recent growth. In the *Boston Medical and Surgical Journal* of Nov. 11th, 1897, Dr. Joel E. Goldhurst describes an important advance on this method made by American surgeons in the last few years—the dissection out of the muscles and their direct re-attachment to others. In a large number of cases of infantile paralysis the sartorius escapes. Being a flexor of the knee its action is useless or harmful when extension is lost from paralysis of the quadriceps. To improve the limb and restore extension Dr. Goldhurst transplants the sartorius and attaches it to the quadriceps tendon just above the patella. He has operated on five patients with marked improvement in three and failure in two which he attributes to imperfect methods of attaching the muscle. He operates as follows. A six-inch longitudinal incision is made on the inner side of the thigh with the middle opposite the top of the patella. The sartorius is dissected out, cut off at its insertion brought forward and attached to the muscular fascia just above and a little to the inner side of the patella. The attachment must be made firmly by splitting the fascia and drawing the muscle through, so that it becomes adherent to both inner and outer surfaces. Kangaroo tendon is used for sutures, being the best material. The wound is then closed and the whole thigh is bandaged and finally a plaster-of-Paris bandage or a long splint is applied. The patient is kept recumbent for two weeks at least, gentle motion is commenced at the end of three weeks, and the plaster is entirely omitted at the end of from five to six weeks. One case was that of a woman, aged twenty-two years, paralysed from early childhood, who had no power of extension or of bearing weight on the limb unless the knee was fixed artificially, and who had a flail-like leg, flinging gait and used a crutch constantly. After the operation, though still somewhat lame, chiefly from weakness of the foot and ankle, the mechanical difficulty at the knee and the gait were almost entirely corrected, the leg was extended normally, and she was able to do housework. A very remarkable result of the operation in the successful cases was hypertrophy of the sartorius causing in one case an increase of half an inch in the circumference of the thigh with concomitant increase in the strength of the muscle until it was able to do the work of the quadriceps. The only other attempt at direct muscular attachment made by Dr. Goldhurst was in a case of infantile paralysis of the anterior tibial muscle producing marked valgus. The method of attaching the tendon of the peroneous tertius or the tendons of the common extensor of the toes to the anterior tibial being liable to failure, in consequence of the small size of the tendons which leads to their sloughing from the manipulations, he performed the following operation. A three-inch longitudinal incision was made over the middle of the anterior surface of the leg. The muscle of the common extensor was dissected out and attached to the anterior tibial muscle by quilted sutures. Some improvement followed, but less than Dr. Goldhurst hoped for.

A MEDICAL POET.

IN the "Arundines Cami" (in which the University of Cambridge took more than chronological precedence of the "Anthologia Oxoniensis" and the "Hesperidum Susurri" of Dublin) are few finer gems than the sonnet on "The Hospice of S. Bernard" and its rendering into the Ovidian distich. The two poems, English and Latin, were particularly admired by the late Dean Milman, who, in his well-known review of the "Arundines," informed his readers that the English poet was Dr. David Macbeth Moir, of Musselburgh and his Latin interpreter Dr. Samuel Butler, Bishop of Lichfield. Physician and divine are long dead, but while both have not been left without memorial it has been widely felt, particularly north of the Tweed, that something more should be done for the former than a brief biographical notice or even than the statue which adorns the old-fashioned fishing-town and golfing-centre in which he practised so honourably. On Jan. 5th, 1898, will recur the anniversary of his birth, and the day has been fitly chosen by a number of leading men in Scottish science and literature to commemorate the "beloved physician" and "tender poet" whose life was a beautiful commentary on the "Songs of the Affections" wherein he was a master. Emeritus Professor Masson, we understand, will be the orator of the occasion and, among other tributes to its hero, he will be able to announce that a "Moir prize," or scholarship, or some substantial award of that nature, will be founded for proficiency in his published writings. The project deserves every encouragement, and we would only suggest to its promoters

Digitized by Google

that Dr. Moir besides being a poet and humourist of genuine capacity was also accomplished in the history of medicine and wrote what was for a long time the only treatise on the subject accessible to the English-speaking world. The connexion between literature and the healing art in their concurrent bearing on the evolution of humanity, its "sorrows and its aspirations," its achievements and its joys might form no inappropriate theme of the prize in contemplation and might one day inspire some exceptionally gifted competitor to embody in lasting prose or verse the spirit of the "medical poet" which breathes so warmly from his own sonnet on "The Hospice of S. Bernard":—

> So task'd to smooth stern Winter's drifting wing,
> And garb the eternal snows in more eternal Spring.

Or in the Cambridge rendering:—

> Temperat et Borem rabiem mollitque pruinas,
> Et facit Æterno Vere tepere nives.

HOSPITAL ABUSE.

A PAPER on this subject is published in the *Medical Magazine* for November by Dr. Herringham, assistant physician to St. Bartholomew's Hospital. Dr. Herringham, if we may so express it, is one of the most sceptical believers in hospital abuse. He takes nothing for granted and he has taken the trouble to go with some minuteness into the social condition of the out-patients of St. Bartholomew's Hospital. The result is that he is doubtful of the great extent of abuse, of the overwork of out-patient physicians and surgeons, and of the propriety of refusing to treat at hospitals the trivial complaints of the poor. He admits, however, that patients are treated free who ought to pay and he advises a concentration of attention on means for exposing such cases. He thinks this is best to be done by a committee of general practitioners in large towns or districts. But surely hospitals should have within themselves the means of ascertaining the fitness of patients. It seems to be a very undesirable duty for general practitioners to have to expose the sins or the shabbiness of their patients. It would be much easier for them to give a note for the admission of fit cases than to act as informants in unfit ones. But Dr. Herringham objects to the suggestion that a certificate of fitness from a medical man should be required. Such a certificate need not be a *sine quâ non* but it might be demanded in all cases which are apparently out of place in a hospital. There is, however, much force in Dr. Herringham's treatment of the subject. He admits the main point, he has no patience with those who abuse hospitals, and would refuse all aid to hospitals which do not employ an efficient and active inquiry officer.

PLAGUE AND PREVENTIVE INOCULATION IN PORTUGUESE INDIA.

WE have received the joint report drawn up by M. Haffkine and Surgeon-Major Lyons upon the recent epidemic of plague in Damaun, Portuguese India, and the effect of preventive inoculation there. The report is of the highest interest, but we have only space to mention a few of the more salient facts. The facts are collected by Professor Koch and Professor Gaffky, with M. Haffkine and Surgeon-Major Lyons, the President of the Bubonic Plague Research Committee; and their informants were His Excellency Colonel J. P. Villar, the Governor; Mr. Judge, the Assistant Collector; Shet Sorabjee, the head of the Parsee community; and six medical officers. The daily mortality from the beginning of March to May 19th, 1897, was 30 per diem—a grand total of 2325 deaths. Of this number 2093 were authenticated in the particular families where they had taken place by means of a house-to-house inquiry set on foot by Shet Sorabjee. Among the Parsee community numbering 306 persons 276 were inoculated twice and 1 once. Of these 1 only died, a woman who had only been inoculated once and that, as was afterwards seen, subsequently to infection by plague. Thus the total mortality among the inoculated Parsees was only 1 in 277—a percentage of 0·36. Among the 29 uninoculated there were 4 deaths—a mortality of 13·8 per cent. Among Shet Sorabjee's servants and labourers, numbering 200 in all, all were inoculated but one. That one was attacked on May 16th and died on May 19th, while among the inoculated 1 person, a child aged four years, was attacked and died. Of other members of the population of Damaun between March 26th and the end of May among 6033 uninoculated there were 1482 deaths, or 24·6 per cent., while among 2197 inoculated there were 36 deaths, or 1·6 per cent. If the inoculated had died in the same ratio as the uninoculated the number of deaths among them would have been 332 instead of 36. Owing to the extreme demand for lymph the latter inoculations were much weaker than those done at the commencement of the epidemic and the difference in favour of the stronger lymph was most marked, for out of 1924 inoculated with the strong lymph there were 70 cases, 3·6 per cent., with 22 deaths, 1·1 per cent., case mortality, 31·4 per cent. Out of 270 treated with weak lymph there were 21 cases, 7·8 per cent., with 14 deaths, 5·2 per cent., case mortality, 66·7 per cent. Figures such as these show the extreme value of the preventive treatment taken as they are from the course of a most virulent epidemic and during the highest stage of the outbreak.

THE Royal College of Surgeons in Ireland announces that a Barker Anatomical Prize of £26 5*s*., open to any student whose name is on the anatomical class list of any school in the United Kingdom, is offered for a dissection of the anterior triangle of the neck, with special reference to the operation of lateral pharyngotomy. The preparations entered must be placed in charge of the curator of the museum before June 1st, 1898, they must be marked with a fictitious signature and accompanied by a sealed envelope bearing outside the same signature and containing the competitor's name.

THE Philadelphia Medical Publishing Company (Box 1573, Philadelphia, Pa.) will begin the publication in January, 1898, of a weekly medical journal to be called the *Philadelphia Medical Journal*. The editorial management has been entrusted to Dr. George M. Gould, whose high reputation as a medical editor guarantees a vigorous and interesting publication.

THE Chairman of the London County Council, Dr. W. J. Collins, was entertained yesterday (Thursday) evening at a complimentary dinner at the Trocadero Restaurant by the staff and former students of St. Bartholomew's Hospital, at which school Dr. Collins received his medical education. Mr. Howard Marsh presided.

WE have received a Report to the Local Government Board on the Preparation and Storage of Glycerinated Calf Vaccine Lymph. The report is the result of a personal tour of inspection on the Continent made recently by Sir Richard Thorne and Dr. S. Monckton Copeman.

DR. H. P. HAWKINS has been appointed Physician to St. Thomas's Hospital in the vacancy caused by the retirement of Dr. W. M. Ord, and Dr. S. G. Toller has been appointed Assistant-Physician in Dr. Hawkins's room.

THE third sitting of the Royal Commission on the Water-Supply of London was held on Monday last in the Moses

Room of the House of Lords. A report of the proceedings will appear in our next issue.

THE Licensed Victuallers' Protection Society have subscribed £1500 to the Prince of Wales's Hospital Fund.

The Lancet Special Commission

ON THE

METROPOLITAN WATER-SUPPLY.

XXII.[1]

NEW RIVER COMPANY—*Concluded.*

THE POND WATER (FOR NON-DOMESTIC SUPPLY).

THE water which is used for drinking purposes is now entirely obtained by the New River Company from the River Lee and from deep wells in the manner described in the preceding articles. In addition to these sources of supply the Company have the right of taking water from a number of ponds which are situated at Hampstead and Highgate. The water is not at the present time used for human consumption. The supply from this source forms a separate system, and is distributed partly for watering roads and other municipal purposes and partly for the supply of the City of London Cattle Market at Camden Town. Cattle, it is said, prefer water derived from ponds to that obtained from wells. Although as a matter of fact there is no doubt that cows prefer to get water from a pond to taking well water from a pail, it does not, of course, necessarily follow that they would prefer the water from the Hampstead and Highgate ponds to that derived from the New River, and with regard to the supply of the Cattle Market it may be said that when there is an insufficiency in the amount of the supply from the ponds the deficiency is made up by filtered water of the same quality as that supplied for drinking purposes to the other part of the New River Company's city district.

The ponds at Hampstead are situated on the Heath. Of those at Highgate some are in Lord Mansfield's Park, Kenwood, and some in Parliament Fields. These latter ones and those at Hampstead are well known to the public, but it is doubtful if very many people know that they are used for the supply of the Cattle Market and that they were till recently the sources of part of the drinking water supplied to Londoners.

At Hampstead Heath there is a disused well which belongs to the Company. It is situated close to the Heath-road and about 250 yards from Hampstead Heath railway station. The well house is an octagonal building and is known locally by the name of the "pepper-box." It is now used as a turncock's residence. The well has a diameter of about 8 ft. and is bricked to a depth of 60 ft. Below this there are iron cylinders which reach down to the chalk. The water in this well is not now used and the pumping engine has been removed, but the well in the past has supplied useful information with regard to the sinking of the underground water in the London district, for careful observations as to the height of the water in the well have now been taken for a long series of years. The level of the water on July 18th was 260 ft. 4 in. from the top of the grids, which is about the same as the ground level and is the point from which the measurements are always taken.

Hampstead Ponds (see Fig. 4).—Of the series of eight ponds at Hampstead one has lately ceased to exist. It has been filled up and the land taken over by the London County Council who have laid out a pleasure garden on its site. This pond, which was called No. 1, was situated between the well and Hampstead Heath railway station. The ponds which remain are all situated higher up the Heath.

Pond No. 2 is close to the well house, it has an area of about four acres.[2] It is supplied by water from the upper ponds and by surface water from the Heath. The water level therefore varies greatly according to the rainfall. The amount of variation is about 5 ft. On July 18th the pond was 4½ ft. "below mark," that is to say below normal high water mark. No water had been drawn from it for a week before this. There is a pipe guarded by a grating, which has 1 in. spaces, at the back of the well house and the water is used for the supply of Camden reservoir. Water comes from a pond No. 3 through a 4 in. iron pipe, and there is an earthenware drain-pipe to conduct the overflow water from Pond No. 3.

Pond No. 3 has an area of about three acres: it is situated to the north of the path leading to Parliament Hill-road and about 20 yards to the north of No. 2, and the level of the water in it is about 25 ft. above it.

Pond No. 4 is situated just to the north of No. 3, and divided from it by a footpath which leads from Parliament Hill to the Heath. It has an area of three acres. The top water-level is about 4 ft. above that of No. 3. At the north-east corner there is a bathing-place which is under the care of the London County Council. This pond is kept at a constant level by the New River Company, so that facilities may be afforded for bathing. The depth and capacity of these ponds are not accurately known. The water which supplies Pond No. 4 comes partly from the Heath through drain-pipes which take off the surface water and partly from the Viaduct Pond which is higher up the Heath, and is now under the guardianship of the London County Council. Some water comes also from the Vale of Health Pond (No. 5)

The Viaduct Pond is supplied by springs and surface water from the Heath.

The Vale of Health Pond (No. 5) is situated at the upper part of Hampstead Heath, about 300 yards from Spaniards-lane. It has an area of about three and a half acres, and is filled with water derived from surface drainage.

Highgate Ponds.—At Highgate there are eight ponds of which the water is used by the New River Company. Of these, the upper ones are in the grounds of Kenwood Park and the lower ones in Parliament Fields. The ponds are numbered from below upwards, the lowest being No. 1 and the highest No. 8

Pond No. 8 is in front of Kenwood House. It is about three acres in extent. From No. 8 water flows over a fixed overflow lip or through a grating. The Company's caretaker has occasionally to remove the weeds which accumulate in the grating, but no other work is necessary here, and the pond is situated in a retired part of the private grounds of of Lord Mansfield's park.

Pond No. 7 is situated at a level of about 12 ft. below No. 8. Its extent is about an acre and a half. The pond is of oblong form. The water passes by an overflow lip guarded by a grating which has one inch spaces.

Pond No. 6 is situated at the lower part of the park, near Millfield-lane, at a level of about 70 ft. below No. 7; it covers about an acre of ground. The water is conducted from No. 7 through pipes.

Pond No. 5 is situated at a level of about 12 ft. below No. 6, and the water is conducted to it through an iron pipe. Its form is more or less crescentic and its area about three acres.

Pond No. 4 is at the lower boundary of the park close to Parliament Fields. Its area is about an acre and a half and the water level is about 20ft. below that of No. 5 from which the water is conducted through a pipe. The other three ponds, Nos. 3, 2 and 1, are situated in Parliament Fields.

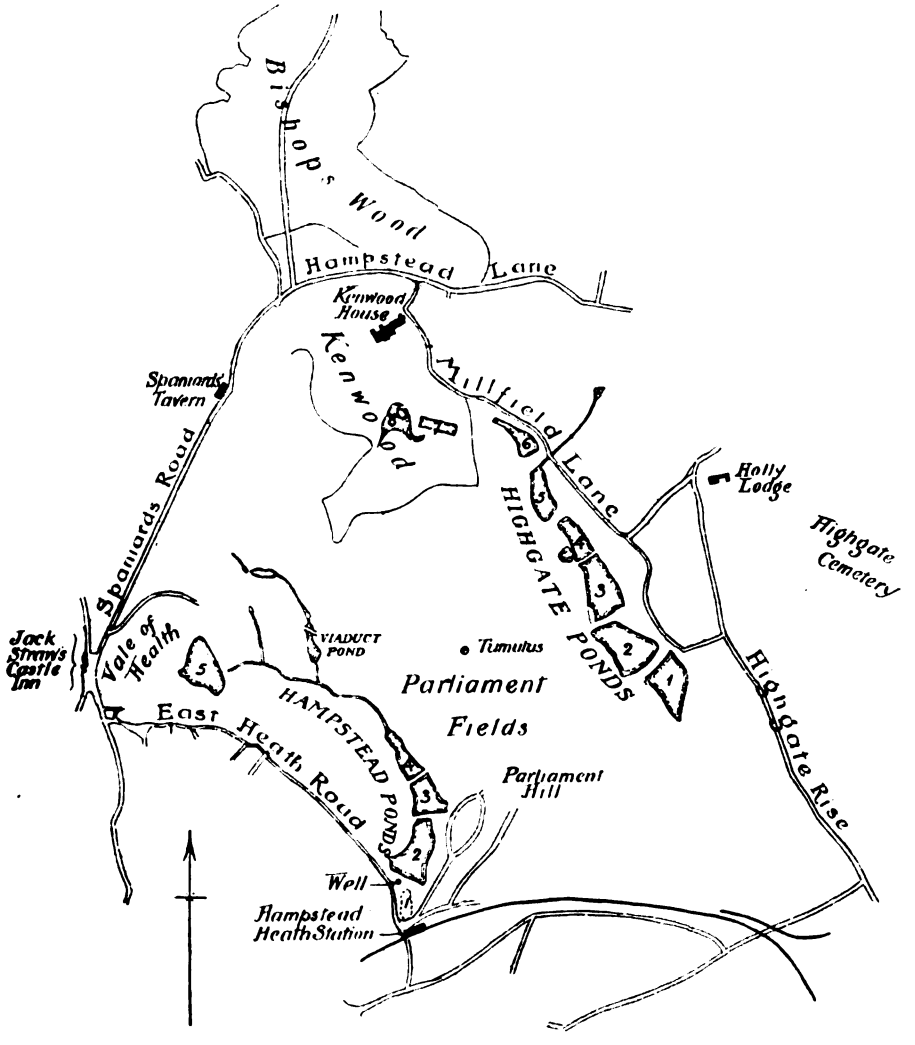
Pond No. 3 has an area of about four and a half acres. Its level is about 3ft. below that of No. 4, from which it receives water through an iron pipe. Water is also obtained from surface drainage. This pond is kept as full as possible and is used for model yacht sailing under restrictions imposed by the London County Council. The overflow from it passes through a 14-in. iron pipe; it is guarded by a grating and the water all goes to Pond No. 2.

Pond No. 2 has an area of about five acres and is situated at a level of 15ft. below that of No. 3; it receives also a certain amount of the surface drainage. This piece of water

[1] Nos. I., II., III., IV., V., VI., VII., VIII., IX., X., XI., XII., XIII., XIV., XV., XVI., XVII., XVIII., XIX., XX., and XXI. were published in THE LANCET of Feb. 20th and 27th, March 6th, 13th, 20th, and 27th, April 3rd, 17th, and 24th, May 1st, 8th, 15th, 22nd, and 29th, June 19th and 26th, Oct. 23rd, Nov. 6th, 13th, and 27th, and Dec. 4th respectively.

[2] The areas and levels here given are approximate only.

Digitized by Google



is used for bathing under the supervision of the London County Council.

Pond No. 1 has an area of about three and a half acres and is situated at a level of 20 ft. below that of No. 2. The water passes to it through an iron pipe guarded by an iron grating. The regulations with regard to keeping the ponds full may be summarised as follows: Nos. 8 and 7 are kept as full as possible; No. 3 is kept full for the convenience of people who sail model yachts; No. 2 for bathers; Nos. 4, 5 and 6 are kept as full as circumstances permit.

Cistern house.—At the southern end of Pond No. 1 there is a small house built over a cistern. The cistern is of brick rendered in cement, about 10 ft. in diameter and 15 ft. in depth, the pipe from the cistern conducts the water at a level of about 6 ft. from the top water level of the pond. The house contains a fireplace and is used for storing rakes and other tools which are used for keeping the ponds in order. A 16-in. pipe conveys the water from the cistern through a garden and then along a foot-path which leads to Highgate-road, thence it passes to the reservoir at Camden Town, a distance of about one and a half miles. Water from the Hampstead ponds is conducted in a pipe which joins this one at Gordon House lane, from which point all the pond water is conducted to Camden-road-square.

Camden Park-road reservoir (see Y on the general map of the Company's works which appeared in THE LANCET of Oct. 23rd, p. 1069).—This reservoir is uncovered. It is situated in an open space. The shape of the reservoir is somewhat peculiar; it may roughly be described as more or less triangular with rounded corners. The sides are built with brick set in cement and are nearly vertical, the slope being about 1 in 12. The top of the surrounding wall has a coping of York stone. The depth of the reservoir is 10 ft. 6 in. There is a large octagonal cock-pit for regulating the supply. The water all comes from the Hampstead and Highgate ponds and is not filtered. It is used for the supply of the Metropolitan Cattle Market. The water, however, is only used for the cattle, the buildings at the market are supplied with filtered water by a separate system of pipes. The reservoir is protected by a spiked iron fence, and a caretaker's cottage is situated here.

FIG. 4.

The Hampstead and Highgate Ponds.

GENERAL STATISTICS.

Length of new pipes.—The length of new pipes, ranging from 3 in. to 36 in. in diameter, laid by the New River Company during the year 1895 was three miles, and in the year 1896 six miles.

New hydrants.—The increase in the number of fire hydrants in use in the metropolis is as follows:—1895, public hydrants, 418; private hydrants, 142; total, 560: 1896, public hydrants, 493; private hydrants, 221; total, 714.

Communications with other companies' mains.—West Middlesex Waterworks Company (1) at the junction of Tottenham Court-road with Oxford-street, and (2) at the junction of Tottenham Court-road with Euston-road.

Digitized by Google

Houses under constant supply.—The number of houses under constant supply on Dec. 31st, 1894, was 100 668; on Dec. 31st, 1895, 109,110; and on Dec. 31st, 1896, 126,409.

Percentage of houses under constant supply.—On Dec. 31st, 1896, the percentage of houses under constant supply was 78.

Average daily supply per head.—The average daily supply per head during the year 1896 was 30·6 gallons.

Highest supply.—The highest supply given is from the standpipe of the reservoir at Hampstead Heath, which standpipe is 486 ft. above ordnance datum.

Dates of maximum and minimum supply.—The following table gives the date of the maximum and minimum supplies and the average daily quantity supplied:—

	Year 1895.		Year 1896.	
—	Month.	Quantity in gallons.	Month.	Quantity in gallons.
Maximum	July	43,121,000	July	43,127,000 daily average.
Minimum	December	32,020,000	December	32,241,000 ,,

Table of Statistical Details compiled from information given by the New River Company for June, 1897.

SUPPLY.	Average daily supply in gallons (filtered)	34,646,498	Total 37,996,000 gallons
	Percentage delivered for other than domestic purposes, exclusive of waste	3,349,502	
	Number of houses supplied	162,169	
	Number of houses on constant supply	129,017	
	Estimated population supplied	1,176,000	
RESERVOIRS. Subsiding and storage unfiltered water	Number	20	
	Area in acres	99½	
	Available capacity in gallons	168,100,000	
Storage filtered water reservoirs	Number	11	
	Capacity in gallons	37,540,000	
ENGINES.	Number	44	
	Horse power	3,910	
	Greatest lift	590	
	Head of pressure in the district supplied	Greatest, 260; least, 40.	
WATER PIPES.	Total number of miles of water pipes	Constantly charged, 649, others, 192; total, 841.	
	Number of miles of water-pipes in the metropolis	Constantly charged, 592; others, 189; total, 781.	
	Number of miles of streets with water pipes constantly charged in the metropolis	389	
	Number of hydrants erected within the metropolis	Public fire, 6517; street watering, 618; private fire, 4296; total, 11,431; and about 12,500 fire-plugs and wash-outs.	
FILTERS.	Number of beds	20	
	Area in acres	16½

AREA OF SUPPLY.

The Act of 1852 authorises the New River Company to supply the following places, some of which are entirely supplied and some partly supplied:—

Supplied.—Barnard's Inn; Ely Place; Ely Rents; Gray's Inn; Hatton Garden; Highgate Hamlet; Holy Trinity; Minories; Lincoln's Inn; Middle Temple; Rolls Liberty; Saffron Hill; St. Andrew, Holborn, above the Bars; St. Clements Danes; St. George, Bloomsbury; St. George the Martyr; St. Giles in the Fields; St. James and St. John, Clerkenwell; St. John the Baptist, Savoy, Strand; St. Luke, Middlesex; St. Mary, Hornsey; St. Mary, Islington; St. Mary-le-Strand; St. Mary, Stoke Newington; St. Paul, Covent Garden; St. Sepulchre Without, Middlesex; Savoy Precincts; Staple Inn; Thavies Inn.

Partly supplied.—Christchurch, Spitalfields; City of London; St. Anne's, Soho; St. Botolph, Aldgate Without; St. James, Westminster; St. John, Hackney; St. John, Hampstead; St. Catherine Precincts (Docks); St. Leonard, Shoreditch; St. Martin in the Fields; St. Mary, Whitechapel; St. Pancras; Westminster; and Norton Folgate.

The Act also authorised the supply of "such other places, if any, in the counties of Hertford and Middlesex out of the Metropolis as the Company now [1852] supply."

The Act of 1854 authorised the supply of the following districts, one of which is entirely supplied, some are partly supplied, some not supplied at all:—

Supplied.—Edmonton.

Partly supplied.—Broxbourne, Cheshunt, Enfield, Great Amwell, Hoddesdon, St. Margarets, Tottenham, and Wormley.

Not supplied.—Little Amwell, St. John (without the Borough of Hertford), and Ware.

NEW WORKS IN PROGRESS AND PROJECTED.

Supply from the Thames.—An Act of Parliament was passed in the year 1896 (59 and 60 Vic., cap. ccxli.) to authorise the West Middlesex Waterworks, the Grand Junction Waterworks Company, and the New River Company to construct new reservoirs at Staines, "and other works for affording an additional supply of water for certain districts north of the Thames." During the last session of Parliament an Act was passed to authorise the Company to make an aqueduct to convey the Thames water into the district supplied. This Act has just been published.

White Webbs.—A new pumping station is in course of erection at White Webbs. A well 200 ft. in depth has been sunk. Below the London clay a layer of Reading or Bagshot sand was found above the chalk. The well is stated to be capable of supplying 2,000,000 gallons of water daily.

THE END.

THE PROPOSED CENTRAL HOSPITAL BOARD FOR LONDON.

A MEETING of the Charity Organisation Society was held at the Royal United Service Institution, Whitehall, on Monday last, Dec. 13th, for the purpose of receiving and adopting the first Report of the General Committee for the promotion of a Central Hospital Board for London.

The Earl of STAMFORD, who presided, in submitting the report detailed the circumstances which led up to the present meeting. On the present occasion the issue would be dealt with by a larger constituency.

The Report stated:—

"The desirability of establishing a central hospital board for London has long been felt by members of the Charity Organisation Society and by many medical men interested in the reform of the system of medical relief in the metropolis. The grounds for this opinion are stated in the opening paragraphs of the pamphlet, containing the scheme for the formation of a central hospital board, circulated in the beginning of the present year. 1. There are (the paragraphs run) in London 12 hospitals with schools, 90 hospitals without schools, 84 charitable and provident dispensaries. It is stated that the number of in-patients dealt with in the course of the past year amounts to 87,119, the number of out-patients to 1,299,132 at the hospitals alone. 2. Besides this voluntary system there are, apart from the hospital accommodation provided for infectious diseases, 26 Poor-law infirmaries dealing with about 10,500 patients daily in addition to those who are inmates of the sick wards of the workhouses; and in the course of the year more than 130,000 'permanent,' 'ordinary,' and 'midwifery' medical orders are issued in connexion with the 44 Poor-law dispensaries of the metropolis. 3. The hospitals and dispensaries are, generally speaking, placed in districts where they were required to meet the demands for medical relief during the last and the earlier part of the present century. The more newly settled population of the last forty years is often ill supplied with

Digitized by Google

hospitals and dispensaries. 4. Any observer of the present state of medical relief in London is struck by these and other facts which indicate the necessity of better organisation. The supply of accommodation is considerable but congested. The out-patients amount to almost incredibly large numbers, showing that after making all allowances far too large a section of the population habitually receive free medical relief. There is a very large Poor-law system of medical relief parallel to that of the voluntary system, but usually working in no fixed or coöperative relation with it. There is little or no cooperation between hospitals. On the contrary, between hospital and hospital the competition is great, so that if one hospital, for instance, is careful in the administration of its out-patient relief department those rightly excluded from it find a ready refuge in a neighbouring hospital, where no questions are asked and no stress is laid on carefulness of administration. The hospitals are often deeply in debt and find it impossible to raise funds sufficient to meet their annual expenditure. New hospitals spring up, often under very doubtful auspices, in regard to the utility and administration of which the general public is unable to form a just opinion. Further, to meet the needs of larger London—to help hospitals, for instance, to extend their accommodation when such an extension is desirable, to help them to move when removal would add to their usefulness—there is no central fund that, applied in conjunction with voluntary contributions, would assist them to develop their resources. Lastly, there is no general system of supervision that while it gives free play to the individual characteristics of individual hospitals insures that defects or abuses are brought to light by inspection and remedied by the common sense of the administrators stimulated by the fear of publicity. The large general hospitals are well and carefully administered; but questions that affect the administration of medical charity in London as a whole receive at present but limited consideration in comparison with the needs and development of individual institutions."

In 1896 "a scheme for a board was elaborated by the Charity Organisation Society, ... and in January, 1897, it was submitted to a special meeting. The main features of the scheme were these—it gave to each hospital definite representation upon a general board. It proposed the formation of a fund for the large and liberal aid of hospitals for special purposes—rebuilding, &c.—on lines similar to those already adopted successfully by the Charity Commissioners in the establishment of polytechnics in the metropolis. It suggested the appointment of an executive committee for carrying out work which a large board could not possibly undertake, while the representation of each hospital upon the general board allowed of ample discussion on all general questions, the adoption of reports, &c. It depended 'not on legal compulsion, but on coöperation and publicity,' and it was drawn up, it was believed, in such a way as not to interfere with hospitals or other medical charities, but to promote coöperation on the following lines: — (1) The preservation of the voluntary system of medical relief; (2) the assistance of hospitals by means of a common fund available for special purposes; (3) the regulation and improvement of the existing voluntary system. Upon the general board representation was given both to general and to special hospitals and to dispensaries and also—a point on which stress was laid — to general practitioners. 'The scheme,' it was stated, 'was not submitted as a "cut-and-dried" proposal, but as a draft which, adopted after further consideration with, possibly, some modifications in detail, is likely to prove a thoroughly useful measure.' A very large number of members of the medical profession in the metropolis and a small number of laymen who were interested in the subject and to whom the scheme was sent gave their names as supporters of the proposal in the following terms: They 'approved generally of the proposal to establish a central hospital board for the metropolis on lines that would ensure a fair representation both of the medical staff and of the lay supporters of the medical charities.' The signatories numbered 1491.

"At the meeting held in January, 1897, the scheme was approved in general terms. ..... The resolution of April, 1896, was confirmed and the draft scheme was accepted 'as indicating a plan that, subject to further consideration, is likely to prove satisfactory.' A general committee was also appointed 'to consider, promote, and from time to time report upon the draft scheme—with power to add to their number and to appoint an executive committee.' The general committee thus appointed and an executive committee have met from time to time. ..... At first the committee discussed the scheme and on some points amended it. Subsequently in March last they issued a paper setting forth the objects of the proposal in the briefest terms as follows:—1. To maintain the voluntary system. 2. To induce coöperation among medical institutions. 3. To act as an advisory body to the public. 4. To advise medical institutions and to assist them in carrying out large improvements, if desirable, by reports to the public and by grants of money as far as the means of the board will admit. 5. To promote the consideration of the hospital and medical needs of London as a whole. The Board shall be representative of all interests. It shall not interfere with the management of individual institutions. It will act by advice and report only. It will not attempt to absorb any of the ordinary monetary resources of the medical institutions but will rely chiefly upon bequests or foundation grants. In 1892 the Select Committee of the House of Lords recommended that a Central Hospital Board for London should be established and the true spirit of their suggestions will be followed. In the scheme of the Select Committee the hospitals and dispensaries were grouped for purposes of representation. After much consideration this plan has been set aside as hardly feasible. The Board will therefore be larger than was at first proposed and it will have to carry on its work with the aid or a duly elected executive and possibly other committees.

"On Feb. 6th the Prince of Wales announced his intention of opening a hospital fund for London in commemoration of the Queen's Jubilee. His Royal Highness wrote: 'Our attention will be concentrated upon an endeavour to secure from £100,000 to £150,000 in annual subscriptions from those who have not hitherto regularly contributed'; and again, as to the distribution of the fund, His Royal Highness stated: 'I am aware that the task of distributing the funds, when collected, will not be without its difficulties. It may be desirable in the future to seek the assistance of representatives chosen by the hospitals, but for the first year we shall rely upon the coöperation of the Distribution Committee of the Hospital Sunday Fund.' Desirous of promoting the establishment of a central board in connexion with His Royal Highness's fund, if that should prove the best method of advance, the General Committee addressed a petition signed by over 1800 persons to his Royal Highness through the Comptroller of His Royal Highness's Household, General Sir Dighton Probyn, in which they prayed that His Royal Highness would distribute his Hospital Fund through a board or council truly representative of the medical charities of the metropolis and of all the interests involved. To this petition Sir Dighton Probyn conveyed by letter a gracious promise from the Prince of Wales that it should be placed before his council."

The report went on to say that with a view to a friendly discussion of the scheme with the hospital authorities deputations from the General Committee, by the courtesy of the boards of the hospitals, attended their meetings and explained the chief objects of the proposal, but the deputations did not receive much encouragement from the boards.

Though disinclined to accept the scheme of the General Committee the general hospitals with schools were moved to take the matter up and the Central Hospital Association has been formed under the title "Central Hospital Council" and consists of in all thirty-six representatives of the general hospitals with schools, three from each hospital, one being in each case a member of the medical staff. The report concludes by stating that during the past year the committee have not attempted to urge the adoption of any single scheme for the formation of a central hospital board. They have rather endeavoured to advance the establishment of such a board under the conditions which appeared most likely to prove successful as public opinion on the subject changed and developed. They propose to adhere to this policy in the future.

Sir W. BROADBENT proposed the following motion:—

"That this meeting adopts the first report of the General Committee for the promotion of a central hospital board for London and expresses its conviction of the great importance of the establishment at an early date of a hospital board representative of all the interests concerned."

This question, he said, had been under discussion for some time and certain misapprehensions had been to some extent removed. One of these was that the movement in favour of a central hospital board was in any way hostile to hospitals. That was disproved by the number of names of hospital physicians and hospital surgeons who supported the movement. The whole object of the movement was to render hospital work of the metropolis more efficient. Another of these misapprehensions had been that the whole movement was an agitation got up by the Charity Organisation Society. The question of hospital abuse had been at various times discussed long before the Charity Organisation Society took it up and there had actually been a committee of the House of Lords for the purpose of finding some means of removing the abuses. At one time anyone who had money to dispose of felt himself perfectly safe in giving that money to hospitals and almost to any hospital; but a feeling of distrust had arisen which it was the object of those who were interested in the movement to remove. It had been shown that many people resorted to hospitals who were not proper subjects for hospital relief and who could well afford to pay for relief. Others were more properly the subjects of parochial relief; and from both sides those who really ought to receive the benefit of hospitals had been hindered and to some extent excluded. He had not attached so much importance to the mere question of numbers as had been felt by some supporters of that movement. He would not care how many people were relieved by hospitals provided they were proper subjects for relief and he was quite sure that hospital physicians and hospital surgeons would be prepared to deal with any numbers so long as the assurance existed that only proper persons came forward. Certain institutions existed under the name of hospitals or dispensaries, &c., which were unnecessary and therefore useless and took money which ought to go to better purposes. The suggestion made on the part of the Charity Organisation Society was that all hospitals should be represented on the Central Hospital Board. This was not a movement on the part of the Charity Organisation Society to get control of the hospitals, to "boss the concern." It was simply a suggestion by which the hospitals should start a self-governing, a self-regulating, central institution, and even when it was so started it was not to have any coercive power or influence; such influence would be indirect. It was proposed also that general practitioners should be represented on this body. On the other hand it had been said that this was a general practitioners' movement. That again was a mistake; general practitioners were not collectively hostile to hospitals. They would sit on the board merely to afford information and assist physicians and surgeons of hospitals and dispensaries in arriving at the best way of removing abuses. He knew of no better way in

Digitized by Google

which guidance could be afforded for the disposition of the different hospital funds than by a representative body such as had been suggested by this committee.

Mr. EDWARD BOND, M.P., who seconded the resolution, said no one could have studied the social organisation of the metropolis without noticing the fact that in many departments of social life there was a curious want of system and of method in several very important departments and he thought that all must allow that there was not very much method or system about the disposition of funds for the relief of the poor by way of medical institutions. Some impression had already been made on the public mind in favour of this scheme and the big hospitals, at all events, had recognised that it would be desirable, so far as they were concerned, that there should be some common board or committee which should consult together for the promotion of common interests. He could not conceive, however, that such a board as they proposed could have a very large or important effect on the organisation of the medical charities of London unless it had behind it some power of the purse and it was his fervent hope that the administration of the fund which the kindness and benevolence of the Prince of Wales had brought together might be entrusted to the control of some such board as had been suggested.

Sir JOSEPH FAYRER strongly supported the resolution because he was convinced that the institution proposed was supremely necessary.

Mr. VICTOR HORSLEY said that he supported the resolution most cordially. He expressed the hope that when the central board was formed it would be truly representative.

Dr. GLOVER said that it was highly desirable that that question should be settled. The present unsettled state of things was having an injurious effect upon hospitals. He also urged upon the committee the desirability of not pressing too dogmatically its views as to the exact composition of the board.

Brigade-Surgeon-Lieutenant-Colonel A. B. R. MYERS said he must oppose the motion though no doubt he was one of a very small minority at this meeting. Many of the managers of the hospitals were very strongly opposed to a central hospital board and he supposed that they felt that it was so impracticable a movement that it was not worth their while to spend their time in coming there to oppose it. In round figures the central board would consist of some 200 members and of course no business could be done. It would be necessary to reduce it by degrees to a very small number of members for practical purposes, then it would not be representative of hospitals at all. Sir William Broadbent had said that the board would not be a coercive one but only advise. Another speaker, however, had let the cat out of the bag by saying that they hoped to get money. If they got money of course they wielded the power and so it was exactly his argument that if the central board obtained those sums of money they were bound to coerce. He admitted that a central board could have many advantages and if it could control the action of the small hospitals that sprang up like mushrooms it would be doing service. He did not believe that such a board would have this control. If they once started a central board it might be the beginning of the destruction of the old hospitals and the commencement of supporting hospitals by the rates. Again, if they had a central hospital board and they controlled the funds of hospitals by one body they would lose the sympathy of the people for individual institutions. People would not subscribe to a central board but rather to institutions in the neighbourhood where they lived and whose work they knew.

Mr. F. WALKER did not think that there was any danger of the hospitals becoming subject to municipal control as an outcome of this board.

Mr. BOUSFIELD supported the motion, remarking that there was a great feeling of distrust in the public mind and that the proposed board would be the best method of dealing with the reforms which were required.

The Rev. E. J. HAND was of opinion that an effective board of the kind under discussion would have to come from Parliamentary or other sanction. The proposed board would not obtain the public confidence unless it were associated with some public body in which the public had confidence—such, for instance, as the Metropolitan Asylums Board or the London County Council. Incidentally he mentioned that the indiscriminate granting of hospital letters constituted a very grave abuse.

Mr. LOCH, the secretary of the Charity Organisation Society, reiterated the remarks of the chairman and other speakers that the Charity Organisation Society did not in any way wish to get the control of hospitals.

The motion was then carried.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on Dec. 9th, 1897, the President, Sir WILLIAM MAC CORMAC, Bart., being in the chair.

A report was received from the Board of Examiners in Dental Surgery. It referred to the recommendations contained in a report of the Dental Education and Examination Committee of the General Medical Council and it pointed out that these recommendations have already been in force under the regulations dated January, 1897. The Board considered that a course of materia medica was undesirable for the reason that dental licentiates not being medical practitioners should not prescribe, and that the course adopted by the Council of the Royal College of Surgeons of England of requiring lectures on the surgery of the mouth and on pathology and of enlarging the practical side of the curriculum, which were not all included in the recommendations of the General Medical Council, are necessary and valuable additions. The Board also reported that they had recognised the Glasgow Dental Hospital as an institution the certificates of which are accepted for the examinations for the licence. The report was adopted.

A report from the Laboratories Committee was adopted. With regard to the preparation of antitoxic serum for the Metropolitan Asylums Board, it was stated that since Oct. 7th the director has supplied 4971 doses of antitoxic serum, each containing 2000 units, for the treatment of diphtheria in the hospitals of the Metropolian Asylums Board, and all the demands have been fully met. During this period, which extended over two instead of the usual three months, 9,954,000 units have been supplied, against 19,650,000 units last quarter (4 months), being a decrease of 9,696,000 units and that in fulfilment of one of the conditions of the grant from the Goldsmith's Company, that antitoxin should be, if possible, supplied for use amongst the poorer classes of the community, the director has continued the supply of antitoxic serum to various general and children's hospitals in London during the past quarter as well as to certain medical practitioners for cases fulfilling the necessary conditions.

On the recommendation of the Committee of Management the Holt Schools of Science and Art, Birkenhead, were added to the list of recognised places of instruction in Chemistry, Physics, and Practical Chemistry, and Charterhouse School, Godalming, was added to the list for Chemistry, Physics, Practical Chemistry, and Elementary Biology.

The PRESIDENT stated that, in pursuance of the resolution of the Council at the last meeting, he had consulted the President of the Royal College of Physicians of London on the question of approaching the Secretary of State for War respecting the conditions of service in the Army Medical Department and they proposed, subject to the approval of the Council, to send a letter to the Secretary of State expressing the hope that it might be possible to amalgamate the Army Medical Staff and Medical Staff Corps into an Army Medical Corps, at the same time conferring real army rank with limited command upon the medical officers and with that rank the military titles which in the army are alone respected, appreciated, and understood.

The Council proceeded to the further consideration of the letter from the Parliamentary Bills Committee of the British Medical Association asking the Council to join a deputation to the Secretary of State for War on the subject of the Army Medical Service. It was decided that the Council would not take part in the proposed deputation and that the Committee should be informed that a letter on the subject had already been sent and that the Council were much indebted to the Committee for the very full and valuable report on the subject which they had sent to the Council.

The PRESIDENT reported the proceedings at the annual

Digitized by Google

meeting of Fellows and Members on Nov. 18th stating that in addition to seventeen members of Council there were present eleven Fellows and fifty-five Members. The Council proceeded to the consideration of the resolutions carried at the meeting and already reported in THE LANCET.

The Council resolved that the mover and the seconder of the first resolution be informed "that the greatest care was taken by the Council to set forth in the elucidatory statement adequately and impartially the question at issue and that nothing advanced at the meeting of Fellows and Members appears to the Council to justify the allegation that the statement was 'misleading and did not adequately represent the facts'"; and that the mover and seconder of the second resolution be informed "that under the existing Charters the Council represent the whole (and therefore all parts) of the corporation, and that in view of the results of the recent poll of Fellows it would be impracticable for the Council even if they thought it desirable to obtain a new charter conferring votes on the Members"; and that the mover and seconder of the third resolution be informed "that the Council are not prepared to make general pronouncement respecting the connexion of Fellows and Members of the College with medical aid associations, but are willing to consider evidence which may be submitted to them respecting the connexion of any individual Fellow or Member with an association which canvasses for patients to the injury of private practitioners and allows the well-to-do classes to take advantages of rates of payment arranged to meet the necessities of the poor."

The PRESIDENT reported the delivery of the Bradshaw lecture on Dec. 8th by Mr. Alfred Willett, the subject of the lecture being "The Correction of Certain Deformities by Operative Measures upon Bones." The Council voted their best thanks to Mr. Willett for his lecture.

The PRESIDENT reported that he had accepted on behalf of the Council the portrait of the late Sir Spencer Wells, Bart., by Rudolf Lehmann, bequeathed to the College by Sir Spencer Wells.

The SECRETARY reminded the Council that a meeting of Fellows would be held at the College on Thursday, Jan. 6th, 1898, at 4 P.M.

A letter was read from the Registrar of the University of London inviting the College by desire of the Senate to nominate representatives to attend a conference on Dec. 14th to consider what steps should be taken in relation to the proposed legislation for the University. The President and Mr. Howes were nominated.

A letter was read from Mr. Thomas Bryant reporting the proceedings of the General Medical Council at their late session. The best thanks of the Council were voted to Mr. Bryant for his services.

A letter was read from the Registrar of the General Medical Council reporting the removal from the Medical Register of a Member of the College. The matter was referred to the Discipline Committee.

A letter addressed to the President was read from Mr. A. W. Senior, M.R.C.S., of Mount House, Levenshulme, forwarding papers relating to a provident association, specifying two cases in which persons with incomes of from £600 to £800 a year and from £400 to £500 a year respectively had been admitted members of the association and asking if anything could be done. This matter also was referred to the Discipline Committee.

A letter was read from the Honorary Secretary of the Jenner Society asking the College to support a memorial to the Government respecting the administration of the Vaccination Acts and to make a contribution to the funds of the society. It was resolved to reply that it was contrary to the custom of the Council of the College to approach the Government in the manner suggested and that the Council had no funds at their disposal for the purpose.

An address was read from the Examiners in Physiology of the College stating that, in consequence of the changes introduced into the curriculum in January, 1892, the student has less time than formerly to devote to the study of physiology, and recommending that an interval of eighteen months should elapse between the First and Second Conjoint Examinations and that a student should have to attend teaching in physiology and histology during the two winter and one summer sessions after passing the First Conjoint Examination before he is allowed to present himself for the Examination in Anatomy and Physiology. The Council referred the address to the Committee of Management for consideration and report.

THE LONDON UNIVERSITY COMMISSION BILL, 1897.

AT a meeting of the Medical School of St. George's Hospital held on Dec. 13th the following resolution was unanimously adopted:—

"The Medical School of St. George's Hospital has taken the London University Commission Bill of 1897 into consideration. The school is of opinion that the provisions of the Bill will need great modification as regards the constitution of the Faculty of Medicine and its Board of Studies if it is to meet the requirements of medical education in London."

At a meeting of the school committee of St. Mary's Hospital held on Dec. 8th it was resolved to send the following letter to the Duke of Devonshire and Mr. Balfour signed by the lecturers and teachers in the medical school of St. Mary's Hospital:—

"We, the undersigned members of the medical and surgical staff of St. Mary's Hospital and lecturers and demonstrators in its medical school, beg to approach Her Majesty's Government with the expression of an earnest hope that the Government in view of the importance of a speedy settlement of the question will introduce early in the approaching session of Parliament a Bill similar to the London University Commission Bill, 1897, and pass it into law during the same session."

A resolution in the following sense was passed at meetings of the Charing-cross Medical School and of the London School of Medicine for Women:—

That the Government is begged to introduce at an early date a Bill, similar to the London University Commission Bill, 1897, for the reconstitution of the London University. Further, it is hoped that upon this occasion the Government will give sufficient time to carry this most important Bill through the House of Commons.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6120 births and 4393 deaths were registered during the week ending Dec. 11th. The annual rate of mortality in these towns which had been 20·2 and 19·8 per 1000 in the two preceding weeks rose again last week to 20·8. In London the rate was 21·8 per 1000 while it averaged 20·2 in the thirty-two provincial towns. The lowest rates in these towns were 14·4 in Cardiff, 14·9 in Newcastle-upon-Tyne, 15·3 in Bradford, and 15·4 in West Ham; the highest rates were 25·3 in Gateshead, 26·4 in Liverpool, 26·7 in Birkenhead, and 34·1 in Norwich. The 4393 deaths included 551 which were referred to the principal zymotic diseases, against 552 and 541 in the two preceding weeks; of these, 231 resulted from measles, 95 from whooping-cough, 85 from diphtheria, 48 from diarrhœa, 47 from "fever" (principally enteric), and 45 from scarlet fever. No death from any of these diseases was recorded last week in Brighton; in the other towns they caused the lowest death-rates in Derby and Cardiff, and the highest rates in Swansea, Burnley, Oldham, and Gateshead. The greatest mortality from measles occurred in Swansea, Birmingham, Burnley, Halifax, Blackburn, Oldham, and Gateshead; from whooping-cough in Bolton and Oldham; and from diarrhœa in Oldham, Burnley, and Bolton. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 85 deaths from diphtheria included 58 in London, 6 in Leeds, and 3 in Wolverhampton. No fatal case of small-pox was registered either in London or in any other of the thirty-three large towns, and no small-pox patients were under treatment in any of the Metropolitan Asylum Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the last week was 3806, against 3792, 3818, and 3812 on the three preceding Saturdays; 319 new cases were admitted during the week, against 397, 375, and 328 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London which had been 471 and 418 in the two preceding weeks rose again to 468 last week and were 40 above the corrected average. The causes of 62, or 1·4 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified

Digitized by Google

in Brighton, Bristol, Oldham, Newcastle-upon-Tyne and in eight other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Birmingham, Liverpool, and Halifax.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns which had increased in the three preceding weeks from 18·5 to 19·6 per 1000 further rose to 20·2 during the week ending Dec. 11th, but was 0·6 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 16·8 in Paisley and 17·2 in Dundee to 28·8 in Greenock and 29·0 in Perth. The 603 deaths in these towns included 20 which were referred to whooping-cough, 17 to diarrhœa, 16 to measles, 12 to scarlet fever, 6 to "fever," and 5 to diphtheria. In all, 76 deaths resulted from these principal zymotic diseases, against 74 and 73 in the two preceding weeks. These 76 deaths were equal to an annual rate of 2·5 per 1000 which was slightly below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough which had been 23 and 22 in the two preceding weeks further declined to 20 last week, of which 14 occurred in Glasgow and 4 in Greenock. The 16 deaths referred to measles showed a slight further increase upon the numbers recorded in recent weeks and included 8 in Glasgow and 8 in Greenock. The fatal cases of scarlet fever which had been 12 and 9 in the two preceding weeks rose again to 12 last week, of which 7 occurred in Glasgow, 2 in Edinburgh, and 2 in Dundee. The 6 deaths referred to different forms of "fever" showed a decline of 2 from the number recorded in the preceding week and included 3 in Glasgow where 2 of the 5 fatal cases of diphtheria also occurred. The deaths from diseases of the respiratory organs in these towns, which had been 123 and 125 in the two preceding weeks, further rose to 129 last week but were 18 below the number in the corresponding period of last year. The causes of 36, or nearly 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.
